Needles rank second in prevalence. We reviewed at least a dozen cases in the English literature, and Cope³ described a case in which the needle was successfully removed.

A recent death caused by a needle in the heart presents several interesting features. There was no definite history of the

On physical examination the patient was markedly dyspneic and apparently acutely ill. We have recorded only the positive physical changes. The blood pressure was 144 systolic, 80 diastolic. The temperature was 100.6 F, pulse rate 130 and respiration rate 40. The left anterolateral portion of the neck and upper part of the chest revealed crepitation on palpation.

The left lower lobe was dull to percussion and almost silent on auscultation. Bubbling rales could be heard at the upper margin of the area of dullness. Over the left upper lobe breath sounds were exaggerated and the percussion note was hyperresonant. No cardiac abnormalities were noted, although the heart sounds were poor.

Blood studies revealed red blood cells 4,210,000, hemoglobin 75 per cent, white blood cells 19,450. The Kahn reaction was negative. The urine showed a heavy trace of albumin.

By the fourth day after admission the interstitial emphysema was disappearing. A thoracentesis on the sixth day yielded no fluid. Bronchoscopy did not reveal a malignant condition of the lung. On the seventh day the heart action became very irregular. Digitalis was given and the rhythm improved.

On the eleventh day the chest was roentgenographed. The roentgenologist reported interstitial emphysema throughout the tissues of the neck and chest wall, left pleural effusion and displacement of the cardiac shadow to the left suggesting atelectasis of the left lung. He observed that increased radiopacity at the periphery of the lung field suggested slight pneumothorax.

The following day the patient was obviously sinking. The temperature rose and the heart rate and respiration rate increased. Death occurred on the evening of the fifteenth day.

Autopsy showed that the left pleural cavity contained 3½ cc. of blood. No puncture wound was found on the pleural surface nor in the fibromuscular tissues of the thoracic wall.

The left lung presented an aerated upper lobe except for a small V-shaped area, about 8 mm wide, at the lower margin of the upper lobe, which overrode the pericardium. This V-shaped area consisted of pleura presenting a perforation from 2 to 3 mm long, occurring at the margin of angulation with collapse and retraction of the underlying alveolar structure. A mechanism for production of the interstitial emphysema noted clinically here was seen. The parietal pleura covering the pericardium at a point opposite this defect presented an area of hemorrhage of approximately 6 mm, to which area thin fibrous strands were attached. The left lower lobe was extensively collapsed.

The parietal pericardium, opposite the area of hemorrhage on the parietal pleura, was covered with coagulated blood. In the midst of the mass adherent to the visceral pericardium which similarly was covered with coagulated blood, the end of a hard sharp object, such as that of a needle, could be palpated. This occurred at a point 5 cm from the apex of the heart and was in general alignment with the perforation of the visceral pleural and pericardial lesions. Close inspection revealed the end of the hard object to be the broken eye end of a thin needle, now black. On dissection, the point of the needle with approximately 1 cm of its length was found projecting into the cavity of the left ventricle after transversing the interventricular septum. The needle was 1 mm thick and 34 mm long.

COMMENT

On the basis of the autopsy and a subsequent history obtained from the patient's widow, it is possible to reconstruct a mod operandi which fits the clinical picture fairly well.

The widow states that the patient stepped on a sharp object in the dark with his left foot in 1932. No foreign object could be discerned in the morning although there was some pain and tenderness of the plantar surface for some days. It would appear probable that this was the point of entrance of the needle which gradually worked its way upward penetrating the pleura and lodging in the heart, the pleural tear caused the interstitial emphysema, while the point in the clinical history at which the heart became irregular probably marked the beginning entrance of the needle into the cardiac structure. The fact that the needle only recently penetrated the pleural pericardial surface was confirmed by the necropsy. It must be considered, however, that the needle may have been driven into the chest recently during one of the falls incident to the patient's vertigo.

Needle in position in the heart exactly as found at autopsy. A1 shows the needle extending through the outer wall of the left ventricle and outlined against the tip of the white arrow. B1 demonstrates the other end of the needle in the inner wall of the left ventricle. A2 represents the blood clot on the parietal pericardium and marks the point at which the needle transversed that tissue. B2 demonstrates the same point on the visceral pericardium. A3 and B3 both represent the small pleural tear that provided a mechanism for the subcutaneous emphysema noted clinically. These points together mark the course of the needle as it entered the heart.

entrance of a needle into the body, an interstitial emphysema involving the neck and chest was the presenting symptom. Pneumothorax and lung collapse followed. The needle was discovered at autopsy. We have not found an identical case in the literature.

A white man aged 70, admitted to the York Hospital, Oct. 28, 1936, had suffered from severe cough and vertigo for four years. For three weeks past there was severe pain in the left side of the chest when he coughed. Dyspnea developed October 26, coughing ceased but the pain in the chest became worse. A physician, called October 28, noted interstitial emphysema involving the left anterolateral surface of the neck and the upper part of the chest anteriorly.

NASAL TUBE GASTRIC SUCTION RESULTING IN
ALKALOSIS AND DEATH

FREDERIC W. TAYLOR, M.D., INDIANAPOLIS

The universal acceptance and use of the constant suction gastric or duodenal tube clearly indicate the desirability and simplicity of this procedure in cases of intestinal obstruction. This life-saving measure has been a greater boon to surgery than any other recent development.

Because of the obvious benefits and the rational use of this apparatus, the dangers and complications of this therapy are apt to be overlooked. In the great majority of cases there is no occasion for fearing any complication. This has given a false sense of security to the routine and indiscriminate use of constant gastric suction. At least this seems to be the case in most surgical services.

In the occasional case this procedure presents a distinct hazard which will not allow its unguarded use. Examples of this danger are illustrated in the following two cases. In retrospect the errors in handling these cases are glaring. Nevertheless, they resulted from routine procedures used in surgical wards countless times with no untoward results.

Errors in the use of gastric suction have not been adequately emphasized in recent literature. Particularly is this true when one is dealing with a patient who has been receiving alkali for peptic ulcer. Because of this the following brief account seems justified.

CASE 1—A man, aged 47, was referred to the Indianapolis City Hospital by Dr. T. P. Rogers Jan. 1, 1937, with a board-like abdomen, epigastric pain and vomiting. A history of peptic ulcer of three years' duration was given. During the past six months the patient had been on a strict ulcer diet (milk, crackers and alkalis). Considerable epigastric discomfort had been present for two weeks before admission, terminating abruptly with an excruciating epigastric pain seven hours before the patient was brought to the hospital.

The temperature was 103 F., white blood cells numbered 15,100 and the urine contained a few pus and epithelial cells but was otherwise normal.

A diagnosis of perforated peptic ulcer was made. Intravenous dextrose solution was started and continued throughout the operation, which was done nine hours after perforation.

Through an upper right rectus incision a perforation 1 cm. in diameter was found in the anterior surface of the duodenum just distal to the pylorus. A simple overlapping of the anterior gastric wall was effected with interrupted silk sutures. Some 400 cc. of turbid fluid and shreds of coagulated milk was aspirated from the right lumbar gutter and pelvis. The abdomen was closed with drainage of the subcutaneous tissue. Considerable difficulty was experienced with the ether anesthesia. The patient's respirations were shallow and would cease entirely for half a minute at a time. This resulted in extreme cyanosis. Because of this only light anesthesia was given. This added to the operative time, which was slightly over one hour. (The full significance of this apnea during anesthesia was not appreciated until later when the patient went into alkalosis.)

When he was sent to the ward, continuous nasal gastric suction was instituted. The patient was allowed to have sips of water by mouth as long as the suction apparatus was working. This practice may be perfectly safe in the usual case but was distinctly harmful in this instance. Various members of his family as well as the nursing staff gave him water. The result was a more or less constant gastric lavage. On the third postoperative day the aspirated fluid reached the extraordinary amount of nearly 9 liters. Following this all gastric aspiration was discontinued.

The patient received 3,000 cc. of dextrose and saline solution daily. These were practically all isotonic and always consisted of at least a liter of saline solution.

The temperature immediately after operation was 103 F. This gradually came down to 99 on the fourth day. From there it rose rapidly to 105.6 shortly before death on the fifth day. The immediate postoperative course was uneventful. There was moderate distention the first day, which was completely controlled with enemas.

On the second postoperative day, a slight cyanosis was noted. This became very marked on the third day. Nothing was found on physical examination to account for the degree of cyanosis that was present. There was no change in the heart, no mediastinal shift or change in auscultation with the exception of a few moist rales at the right base. The patient felt fine and certainly did not share the concern of his attending physicians. The abdomen was scaphoid and the temperature was coming down.

The morning of the fourth day the patient was deeply cyanotic, apathetic and disoriented. He was having tetanic seizures with carpopedal spasm. Ankle clonus and extremely active deep reflexes were present. The respirations were decreased to nine shallow excursions a minute. It was at this time that a chloride deficiency and alkalosis was even considered as being responsible for the patient's condition.

Dr. Paul J. Fouts of the medical service was asked to see the patient and ordered immediate determinations of the blood chloride and carbon dioxide combining power. These confirmed the diagnosis of alkalosis, with values for the blood chloride of 306.5 mg. (sodium chloride in plasma) and for the carbon dioxide combining power of 123 volumes per cent.

The urinary output, which had been ample up to this time, diminished to 100 cc. for twenty-four hours.

Following the laboratory examinations, massive amounts of fluid were given intravenously. This totaled 7,600 cc. for the next twenty-four hours and contained approximately 90 Gm. of sodium chloride. Two liters of these fluids was given in the form of Hartman's solution and one contained 5 per cent dextrose. Ammonium chloride, 6 Gm., was given twice by rectum.

The following day (fifth postoperative) the patient seemed generally weaker and still was deeply cyanotic, though respirations were normal in rate and depth. The plasma sodium chloride was 533 mg. and the carbon dioxide combining power was 87 volumes per cent. The patient's temperature rose to 104 and many rales were heard throughout both lung bases. The urinary output for the previous twenty-four hours was 70 cc. The patient was given 100 cc. of 50 per cent dextrose intravenously. This caused no change in condition and resulted in no urinary output. During a second administration of dextrose later in the day the patient died.

Unfortunately a blood urea determination was not done. That it was markedly elevated there can be no doubt, since this is a characteristic feature of alkalosis and since the urinary output was so markedly diminished.

Permission for autopsy was obtained and revealed marked congestion and edema of the lungs with hypostatic bronchopneumonia at the bases. A local fibrinous peritonitis was found about the area of perforation and in the pelvis. A moderate amount of turbid fluid was present in the general peritoneal cavity. The ulcer repair was still tightly sealed. Microscopic changes in the kidneys included interstitial scarring, edema and round cell infiltration. There were a few hyalinized glomeruli and moderate degenerative changes in the convoluted tubules. Cellular debris and many casts were found in these and in the straight tubules.

There was insufficient evidence in the autopsy in case 1 to account for death, with the exception of the terminal hypostatic pneumonia. The alkalosis apparently was not a final deciding factor, as evidenced by the improvement shown by laboratory examination and lack of tetany and apnea during the last day. It is assumed then that, though the patient lived for thirty hours after alkalosis was diagnosed, too much renal damage had taken place in an already inferior renal tissue to allow recovery.

The association of renal insufficiency developing in alkalosis is well known. Also the frequency with which mild or even severe alkalosis may develop in ulcer patients receiving alkali has been frequently discussed and needs no elaboration here.

Cyanosis as a sign in alkalosis is not well understood or appreciated. This relationship was discussed by Koehler¹ in reporting cases in which alkalosis developed as a result of alkali therapy. Koehler felt that cyanosis resulted from a disturbance in the shift of the chlorine ion between plasma and red

¹ Koehler, A. E. Acid Base Equilibrium. *Arch. Int. Med.* 31: 590 (April) 1923.

blood corpuscle. This was thought to interfere with the formation of oxyhemoglobin. Partial confirmation of this view is found in the work of Morris². Whatever the mechanism, it must have persisted after the alkalosis came under control in the case under discussion. This is evidenced by the fact that the cyanosis continued unchanged even with the elevation of the blood chlorides and the decrease in carbon dioxide combining power.

If the same problem should arise again it is difficult to say how the therapy should be changed. Possibly the sodium chloride was given too rapidly. Cooke³ is of the opinion that acidotic drugs (ammonium chloride in this instance) do not hasten recovery and in large doses may actually be dangerous. The real therapy consists in anticipation and prevention of alkalosis.

CASE 2—A youth, aged 18, occupied a bed adjacent to the patient just discussed. He had been operated on for a perforated peptic ulcer just two days before the operation in case 1. There was no previous history of ulcer and perforation occurred while the stomach was empty. Repair was effected in an identical manner as in case 1 four hours after perforation. The boy was making a nice, uneventful recovery. The nasal gastric suction apparatus, which was started immediately after operation, was removed on the fifth day. Water and fruit juices were allowed by mouth.

Because of considerable gastric retention, aspiration of the stomach was done night and morning. This resulted in the removal of amounts of fluid varying between 800 and 1,200 cc.

The patient complained slightly of a light-headed sensation. He was also unduly anxious about his condition for one of his age. This was especially true in view of the fact that his wound was healing nicely, the abdomen was scaphoid and soft, and he had no fever. On the morning following the death of the first patient, the boy was more carefully examined. Nothing was found except a slight but definite cyanosis of the lips. Because of this, blood chloride and carbon dioxide studies were ordered. The blood chloride reported as sodium chloride in the plasma was 348.5 mg., while the carbon dioxide combining power was 84.6 volumes per cent.

The diagnosis of alkalosis was made and the patient was given 2,000 cc. physiologic solution of sodium chloride intravenously. The periodic aspirations of the stomach were stopped. Cyanosis was not noted the following day (eighth post-operative day) and the patient seemed much improved mentally. Laboratory studies gave blood chloride 415 mg. and carbon dioxide combining power 90.5 volumes per cent. The slight rise in the latter figure over that of the previous day remains unexplained.

The patient received more intravenous salt solution and was put on a frequent feeding soft diet. From this time on his convalescence was uneventful.

COMMENT

From these experiences several precautionary measures are suggested in the use of nasal gastric suction.

1. Ulcer patients receiving alkalis are frequently in mild alkalosis as a result of this therapy. They therefore demand particular care.

2. These patients are poor anesthetic risks.⁴ When possible, alkalis should be stopped several days prior to an elective operation. Water and salt should be forced during this period.

3. The association of renal insufficiencies and alkalosis in treatment of peptic ulcer is a frequent occurrence.

4. The routine and indiscriminate use of the nasal gastric suction apparatus is extremely hazardous in the occasional case. This is particularly true when used for peptic ulcer.

5. The amount of drainage by this route should be measured daily and this amount added to the patient's fluid requirement. The quantity of chloride thus removed must be fully covered with intravenous saline solution.

6. There is a real danger in allowing sips of water by mouth to the patient with gastric suction. In excess (case 1) this acts as a constant gastric lavage adding to the chloride loss.

7. Cyanosis is suggestive evidence of alkalosis as well as tetany, hyperactive reflexes, nervousness, introspective attitude, headache and the like.

8. A case of alkalosis here reported resulted in death following the routine and uncontrolled use of the nasal gastric suction apparatus.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE USE OF EXPECTORANTS

CHARLES L. BROWN, M.D.

PHILADELPHIA

This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed

An expectorant may be defined as a medicine which aids in the removal of mucus or exudate from the lungs, bronchi and trachea. This action may be accomplished by causing a more active secretion, or by making the sputum more liquid or less tenacious. Another means of removal of sputum would be to stimulate the act of coughing, but this is seldom necessary or wise except in unusual states of debility in which large accumulations of sputum may actually imperil the patient. Often such a method would result in an expenditure of precious energy, and if possible aspiration should be employed instead. Coughing is nature's most efficient method of raising and ejecting sputum, and in some instances in which coughing is excessive, therapy must aim at controlling this act to allow the patient physical and mental rest and allow coughing at a time when it can be most efficacious.

To cough is to expel air, mucus or exudate from the lungs or air passages in a noisy, violent manner. When the respiratory mucosa is irritated by congestion, exudate or for some other reason, the nerve fibers transmit the impulse to the respiratory center and the rather complex act of coughing is excited. Deep inspiration occurs, the glottis closes, and forced expiration is made. When the pressure becomes great enough to open the glottis, the sudden change in pressure is attended by the expulsion of a blast of air which characterizes the cough. If mucus or exudate is present in the lower respiratory tract it may be ejected with the air and the cough is "productive." If little or no exudate is present, or no sputum can be raised because of tenaciousness or for other reasons, the cough is said to be "dry" or "unproductive."

In respiratory tract disease in which bronchial obstruction, diffuse or localized, is a part of the picture there is a derangement of intrapulmonic and intrapleural pressures, the extreme of which is found in

pulmonary emphysema Mucus or exudate may cause partial bronchial obstruction to both inspiration and expiration The forces of expiration are not as great as those of inspiration, and emphysema results from the accumulation of air in the alveoli and overdistention of their walls Efforts to inspire air past the obstruction may be attended by increased negative intrapleural pressure, but if expiration is impeded greatly, as in obstructive emphysema, intrapleural pressure becomes elevated positively In coughing, the forced expiration is accompanied by increased intrapulmonary pressure and elevated intrapleural pressure, simulating transiently the pressure changes found in emphysema, and, therefore, frequent prolonged unproductive coughing may be harmful Since obstruction due to bronchial spasm or accumulation of sputum may respond to medication, these factors should be carefully evaluated in the selection of expectorants

Indications for expectorants most often arise in inflammatory conditions of the lungs and larger air passages, and since the same expectorant may not be efficient or advisable in the different stages of the disease, the proper selection depends on a thorough understanding of the underlying pathologic condition In allergic manifestations, as bronchial asthma and asthmatic bronchitis, the degree of bronchial spasm and the character of the accumulated secretion serve as excellent guides in the choice of therapy The clinical interpretation of the pathologic process is aided greatly by the close observation of the type of cough and expectoration Furthermore, the art and science of the prescribing of expectorants is dependent on appraisal of the type of cough, the character of the sputum, and the correlation with the stages and clinical features of the causative disease Four rather distinct types of cough may be recognized the hacking, irritative unproductive cough, the "tight" cough with scanty or tenacious sputum, the wheezy, squeaking cough, which may be either dry or productive, and the "loose" cough with abundant sputum In consideration of the subject under discussion, sputum has three main constituents, water, mucus and purulent exudate, and in the individual case it is necessary to evaluate the relative proportions of these components In the early congestive stage of acute tracheitis, and bronchitis, the cough is of the hacking, irritative, unproductive type After a few hours or even as much as from one to three days later it may become a "tight" cough with scanty or tenacious mucoid sputum In some cases of acute bronchitis, the squeaking, wheezing cough develops Later in the disease the sputum becomes more abundant and mucopurulent and the cough loose Bronchopneumonia may provide a similar change in the cough and sputum Lobar pneumonia often has a type of cough and sputum characteristic of the disease, but generally the early stage has a tight grunting cough with a scanty, more tenacious mucopurulent and rusty sputum, while in the later stages the cough is loose and there is abundant, more purulent, sputum Chronic bronchitis produces a thicker mucopurulent sputum, which at times is tight, at other times loose, depending on the abundance of the sputum, on the relative amounts of pus and mucus, and on associated bronchial spasm, and at times the cough may have a wheezy character The cough of congestive heart failure is often rather unproductive until secondary infection in the bronchi or lungs appears, then it simulates that of

chronic bronchitis If pulmonary edema occurs, the sputum is abundant, watery and frothy, and may be blood tinged The wheezing, squeaking cough is characteristic of bronchial obstruction and is the type found in asthma and asthmatic bronchitis, and here the sputum is scant at first, later more abundant, and is tenacious and contains varying amounts of mucus and pus, depending on an associated bronchitis In chronic pulmonary disease a loose cough with abundant purulent sputum usually means pulmonary suppuration with cavity, such as lung abscess, suppurative pneumonitis or bronchiectasis In the latter conditions, coughing occurs when the exudate reaches the irritable level in the air passages, since the deeper portions of the lungs are rather insensitive to stimulation, thus the reason for postural drainage in such cases The odor of the sputum may be a very good index as to the prolonged retention in the suppurating area Although older writings have described a characteristic cough and sputum of tuberculosis, it is now recognized that almost any of the types mentioned may be found in pulmonary tuberculosis, depending on the type of pathologic process present As a general rule the appearance of gross blood in the sputum of chronic pulmonary disease calls for pulmonary rest

Since the beginning of medicine the patient with a cough has expected and often demanded a "cough medicine" as part of the treatment A review of old authoritative works on therapeutics reveals numerous drugs of one kind and another used for this purpose, a great many of them now obsolete, and provides an interesting historical background in therapy Indeed, it would seem that the use of expectorants has been more of an art than a science

Usually an expectorant is classified as "stimulant" or "sedative," and Sollmann¹ has included a third group, the "anodyne expectorants" Perhaps such a classification serves some useful purpose, although it is difficult to list accurately the expectorant drugs under these three headings There is some confusion in the definition of these terms, for example, one medical dictionary² defines a stimulant expectorant as one "used to expel secretions already formed", one textbook on therapeutics³ refers to stimulant expectorants as those "which are largely excreted in the bronchial mucus and which check the secretion or modify its character in some obscure way", Fantus⁴ defines this class of expectorants as "aromatic bodies that owe their virtue to elimination from the bronchial mucous membrane Given in sufficient dosage, they possibly tend to favor healing by producing a curative hyperemia" Bethea, referring to Sollmann's classification, gives a practical correlation and clinical guidance as follows

Sedative Expectorants They are intended to soothe the acute inflammation mainly by stimulating the secretion of protective mucus They may be nauseants as ipecac, demulcents, as acacia or glycyrrhiza, salines, as ammonium chloride, alkalis, as ammonium carbonate **Irritant (stimulant) Expectorants** These are intended to irritate the mucous membranes in such a way as to stimulate repair They also tend to diminish excessive secretion Some of these are also called aromatic expectorants Typical of this group are terpin hydrate and creosote

Anodyne Expectorants These are intended to depress the excessive cough reflex. These tend usually to diminish secretion. Codeine is typical.

Accordingly, the expectorant drugs official in the U. S. Pharmacopeia XI may be listed as in the accompanying table.

Expectorant Drugs

Sedative Expectorants	Calci Creosotas
Ammonii Chloridum	Guaiacol
Ammonii Carbonas	Eucalyptol
Liquor Ammonii Acetatis	Oleum Eucalypti
Potassii Acetas	Oleum Picis Rectificatum (Oil of Tar)
Potassii Citras	Syrupus Picis Pini
Sodii Citras	Oleum Terebinthinæ
Syrupus Acidi Hydriodici	Terebenthinum
Potassii Iodidum	Terpini Hydras
Calci Iodobehenas	Oleum Pini Pumilionis
Antimonii et Potassii Tartras	Syrupus Scillæ
Apomorphinæ Hydrochloridum	
Syrupus Ipecacuanhæ	
Mistura Opii et Glycyrrhizæ	Anodynes
Composita (Brown Mixture)	Morphinæ Sulfas
	Codeinæ Sulfas
Stimulant Expectorants	Codeinæ Phosphas
Creosotum	Aethylmorphinæ Hydrochloridum
Creosoti Carbonas	

Ammonium Chloride—Ammonium chloride causes the sputum to be more fluid and less tenacious and may increase the quantity. Therefore, it is useful in the "tight" cough accompanied by scanty or tenacious sputum, and this is most often seen in the acute and subacute inflammatory conditions (bronchitis and pneumonia) and asthma. Ammonium chloride is not indicated in the chronic stages when the sputum has become more abundant and easy to raise. Its effect does not last long and it should therefore be given at frequent intervals, perhaps as often as every two hours, and usually the dose of 5 grains (0.3 Gm.) is satisfactory. It should not be prescribed with alkali hydroxides or carbonates. The following vehicles are especially suitable for ammonium chloride: syrup of citric acid, syrup of cherry, syrup of wild cherry, syrup of acacia, syrup of tolu balsam and elixir of glycyrrhiza.

Ammonium Carbonate—This drug has much the same indications as does ammonium chloride, although it is more irritating to the throat and stomach and in large doses may act as a nauseant. With regard to dosage and frequency of administration, it should be used in much the same way as ammonium chloride. It is incompatible with acids and should not be prescribed with the syrups of acid reaction, such as those of citric acid, squill and ipecac. Although carbonates precipitate free alkaloids from aqueous solutions of most alkaloidal salts, codeine and atropine are not precipitated by ammonium carbonate.

Suitable vehicles for ammonium carbonate are syrup of acacia, elixir of glycyrrhiza and syrup of tolu balsam. Additional flavoring may be helpful in disguising the unpleasant taste, and for this purpose anise water, peppermint water and compound tincture of cardamom may be used.

Citrates and Acetates—Although some of the citrates and acetates have been used in the acute respiratory infections for their diuretic and indirect alkalinizing effect, they have been listed also among the expectorants, especially in larger doses by many physicians. Representative of this group of drugs are sodium and potassium citrates and solution of ammonium acetate and potassium acetate. When the citrates are to be used, the sodium citrate is commonly chosen and should be given in doses of 15 grains (1 Gm.) every two hours, taken with at least 3 ounces (90 cc.) of water.

Either the sodium or the potassium citrate may be nicely prescribed in the syrup of citric acid or the syrup of orange. The acetates are somewhat less palatable and two common representatives of this group are solution of ammonium acetate and potassium acetate. The solution of ammonium acetate (liquor ammonii acetatis) is made from ammonium carbonate and acetic acid and should be used only when freshly prepared. The average dose is one-half ounce (15 cc.) and is best given in one of the aromatic waters and flavored syrups. Peppermint is especially recommended as a flavor. If acetates are to be prescribed, potassium acetate in 1 to 30 grain (1 to 2 Gm.) doses in one of the aromatic waters and flavoring syrups is recommended.

Iodides—Fantus¹ states that "iodide is the most powerful agent available for producing hyperemia and exciting secretion of the respiratory mucous membrane," and "therefore it is contraindicated in acute bronchitis." By the same reasoning it is contraindicated in other acute forms of respiratory infection, such as the early stages of pneumonia. When the pathologic process is older and the sputum more tenacious, or in asthma or asthmatic bronchitis, the iodides may be very helpful. They are used against a thick sputum. Three official forms may be mentioned: potassium iodide, syrup of hydriodic acid, and calcium iodobehenate. The average doses given for these drugs are potassium iodide 5 grains (0.3 Gm.), syrup of hydriodic acid, 4 cc., calcium iodobehenate 8 grains (0.5 Gm.). If one considers only the iodine content in these drugs in the doses given, the amount of iodine is not comparable, the potassium iodide containing the most, the calcium iodobehenate being next, and the syrup of hydriodic acid containing the least. Potassium iodide is the simplest and most efficient form to prescribe if the iodide effect is desired. As saturated solution it may be given in five drop doses in milk after meals, or it may be prescribed in syrup of tolu balsam, syrup of orange, syrup of cherry or syrup of wild cherry, and syrup of pine tar. Syrup of hydriodic acid, in drachm (4 cc.) doses every three or four hours, is prescribed ordinarily as such. The calcium iodobehenate is especially useful in cases in which potassium iodide causes gastric irritation and may be prescribed in its pure form without any vehicle.

Iodide should not be used in any case suspected of tuberculosis because of the danger of its increasing the activity of the disease.

Among the expectorants which are effective because of their nauseant action are ipecac, antimony and apomorphine. This group is indicated in acute respiratory infection in the early congestive stage when there is a "dry" cough. The official preparations have been listed. Of these ipecac probably is the most used now and is especially employed in the acute laryngeal, tracheal and bronchial inflammations in children. The syrup of ipecac may be prescribed as such, the dose being from 5 to 12 minims (0.3 to 0.7 cc.), or it may be combined with some other expectorant indicated in the early inflammatory stage. Syrup of orange and syrup of tolu balsam are suitable vehicles for ipecac. Antimony in some form was formerly used widely as an expectorant but has become less popular. Antimony and potassium tartrate is commonly employed, the dose ranging from $\frac{1}{60}$ to $\frac{1}{20}$ grain (1 to 3 mg.), and syrup of glycyrrhiza, of orange or of tolu balsam make satisfactory vehicle. A large part of the expectorant action of the compound mixture of glycyrrhiza (brown

mixture) may be attributed to its antimony content. Apomorphine hydrochloride is most often given subcutaneously, the average dose being $\frac{1}{60}$ gram (1 mg), although a satisfactory effect may be obtained by mouth.

The stimulant sedatives are most useful in the chronic inflammatory conditions. They tend to lessen the mucus and exudate and the hyperemia caused by them may aid the healing process. They should not be used in the acute stage because of the tendency to produce hyperemia. Creosote compounds and terpin hydrate, both aromatic, are the representatives of this group which will be discussed here. Both calcium creosotate and creosote carbonate are satisfactory preparations and are used much the same. The average dose of calcium creosotate is 8 grains (0.5 Gm) and of creosote carbonate 15 grains (1 Gm). Doses should be smaller at first. Usually an interval of four hours between doses is satisfactory. These drugs are especially useful when the sputum is abundant, as in lung abscess, bronchiectasis and suppurative pneumonitis. Many patients indicate that the sputum becomes less objectionable in taste and odor after taking these. Calcium creosotate is best given in tablets. Creosote carbonate, in ascending (drop) doses, should be shaken up with milk.

Terpin hydrate is indicated in the chronic cough with abundant sputum and is said to be helpful especially against an excessive liquid sputum. It is commonly used in the form of elixir of terpin hydrate, which contains an insufficient quantity of terpin hydrate to give the best effect. For the full effect it is better to give terpin hydrate in capsules containing from 2 to 5 grains (0.13 to 0.3 Gm) three or four times a day. Elixir of terpin hydrate serves as a suitable vehicle for codeine.

Squill, not an aromatic but classified as a stimulant expectorant, has been used considerably in acute bronchial inflammation of children and in "spasmodic croup," as the syrup of squill, usually in doses of from 15 to 30 minims (1 to 2 cc). At one time it was also said to be helpful in the "winter bronchitis" of the aged. In the latter instance its good effect no doubt was related to the cardiac element in the so-called bronchitis. The syrup contains sufficient squill, if given in frequent doses, to produce some "digitalis-like" effect and this should be kept in mind in its usage. The syrups mentioned are suitable vehicles, and other expectorants are sometimes added. Ammonium carbonate should not be put in syrup of squill.

The anodyne expectorants, so called, hardly need any comment, except to caution against their use in cases in which there is abundant purulent sputum. The purpose of the cough is to get rid of this exudate, and suppression of the cough reflex may be hazardous. Nevertheless, they are useful in giving the patient rest if coughing in such cases has tended to cause exhaustion. These drugs act by allaying the cough reflex, and the dose and frequency of administration are an individual problem. Codeine sulfate or phosphate are ones of choice, morphine should be avoided in treatment of the chronic cough because of the danger of addiction. However, there are occasions when good clinical judgment may dictate its use for temporary relief.

Diffuse partial bronchial obstruction as exemplified in bronchial asthma and asthmatic bronchitis presents a special problem in the use of expectorants. Both

bronchial constriction and plugging by tenacious mucus enter into this mechanism. Solution of epinephrine 1:1,000, in doses of from 3 to 12 minims (0.2 to 0.7 cc) given intramuscularly, is the most effective remedy for the bronchial spasm. Ephedrine hydrochloride and sulfate have a more prolonged effect and have the advantage of oral administration but are less certain to give relief. The ephedrine compounds in capsules are satisfactory, although they may be put in liquid preparations. Stramonium and belladonna, usually given as the tincture in a vehicle and often combined with some other expectorant, tend to diminish the quantity of the bronchial secretions. Potassium iodide is helpful in combating tenaciousness of sputum.

The availability of so many expectorants may cause difficulty in choice for a particular case. Most of the

PRESCRIPTION 1—For Acute Bronchitis or Pneumonia

R	Ammonium chloride	10 Gm
	Elixir of glycyrrhiza	60 cc
	Syrup of acacia	to make 120 cc
M S	One teaspoonful in half a glass of water every two hours	

PRESCRIPTION 2—For Acute Bronchitis or Pneumonia

R	Ammonium chloride	10 Gm
	Syrup of citric acid	to make 120 cc
M S	One teaspoonful in half a glass of water every two hours	

PRESCRIPTION 3—For Acute Bronchitis or Pneumonia

R	Ammonium carbonate	10 Gm
	Compound tincture of cardamom	30 cc
	Syrup of tolu balsam	to make 120 cc
M S	One teaspoonful in half a glass of water every two hours	

PRESCRIPTION 4—For Subacute or Chronic Conditions

R	Potassium iodide	10 Gm
	Syrup of tolu balsam	to make 120 cc
M S	One teaspoonful three times a day after meals	

PRESCRIPTION 5—For Asthma or Asthmatic Bronchitis

R	Potassium iodide	15 Gm
	Tincture of stramonium	20 cc
	Syrup of tolu balsam	to make 120 cc
M S	One teaspoonful three times a day after meals	

PRESCRIPTION 6—For Children

R	Syrup of ipecac	5 cc
	Syrup of orange	to make 60 cc
M S	One teaspoonful every three hours as necessary for cough	

PRESCRIPTION 7—For Acute Conditions

R	Compound mixture of opium and glycyrrhiza	120 cc
S	One teaspoonful every three hours as necessary for cough	

therapeutic demands can be satisfied by skilful employment of a few representative drugs such as ammonium chloride, potassium iodide, syrup of ipecac, calcium creosotate, terpin hydrate, codeine phosphate, epinephrine, ephedrine sulfate and tincture of belladonna. The selection of a suitable vehicle may be of no little importance in commanding the respect and cooperation of the patient. Syrups of acacia, tolu balsam, cherry, wild cherry and citric acid and elixir of glycyrrhiza furnish a fairly adequate choice.

Of the accompanying typical prescriptions, 1, 2 and 3 are to be used in acute or subacute inflammatory conditions (acute bronchitis, pneumonia) at a time when the cough is "tight" and the sputum is scanty.

Prescriptions 4 and 5 are to be used in subacute or chronic inflammatory conditions when the sputum is thick, tenacious and more abundant. (Caution: Not to be used in tuberculosis.)

Prescriptions 6 and 7 are to be used in acute inflammatory conditions when the cough is dry or the sputum scanty.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER Secretary

FISCHERTHERM SHORT WAVE DIATHERMY UNIT MODEL 104-B ACCEPTABLE

Manufacturer The Fischer Corporation, Glendale, Calif
The Fischertherm Model 104-B is recommended for medical and surgical use. In construction it is essentially the same as the Fischertherm previously accepted by the Council.¹ The chief difference is that the new machine is arranged for an "inductance cable." The wavelength, checked by an absorption wave meter, was found to remain within 0.5 meter of rated value of 15 meters when working varying loads. The maximum input is said to be 900 watts. Since there is no acceptable method for measuring the output power of short wave machines, this value is not given.

Fischertherm
Short Wave
Diathermy Unit
Model 104-B

The firm was asked to furnish evidence to substantiate the efficacy of the "inductance cable" method of application. A reliable investigator compared heating efficiency of this technique with conventional diathermy. The temperature observations were made on reliable and carefully calibrated equipment, which had been accurately checked by a competent physicist.

Twelve observations were made on each machine. Six healthy male medical students were used for subjects. Experiments were conducted on the left and right thigh alternately.

Temperature measurements were observed with the thermocouple in the anterior portion of the thigh at depths of one-eighth inch, three-fourths inch, 2 inches or against the bone. These depths were measured from the skin straight in—that is, normal to the surface of the skin.

For the conventional diathermy treatments, block tin electrodes were placed on the medial and lateral aspects of the thigh and held firmly in contact with bandaging. In applying the

Schematic Diagram of Circuit

inductive cable approximately one inch of bath toweling was wrapped round the thigh and it was held in place by approximately four wraps of the inductive cable. Room temperature throughout the day remained between 74 and 78 F and the wet bulb temperature varied from 60 to 66 F.

Each item given in the accompanying tables is an average of twelve observations, application by the inductance cable in the first table and by block tin electrodes in the second.

The temperature rise of the transformer, after the machine was operated at full load for two hours, came within the limits of safety prescribed by the Council. The total shipping weight

is about 85 pounds. Burns may be produced but can be avoided by taking proper precautions when applying the applicators.

The Fischertherm was referred to a clinic acceptable to the Council for investigation and found to give satisfaction in actual practice.

In view of the foregoing favorable report, based on the performance of the unit with the inductance cable, and the

evidence previously submitted on cuff electrodes and surgical electrodes, the Council on Physical Therapy voted to include the Fischertherm, Model 104-B, Short Wave Unit, in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

EDWENIL NOT ACCEPTABLE FOR N N R (II)

In 1933 the Council declared Edwenil unacceptable for inclusion in New and Nonofficial Remedies because it was apparently an unscientific preparation of semisecret composition, marketed under an uninformative name with unwarranted and possibly dangerous therapeutic claims (THE JOURNAL, Oct 7, 1933, p 1154). As brought out at that time, Edwenil is a product proposed for nonspecific immune therapy, marketed in the United States by Spicer and Company of Glendale, Calif. It has been variously designated "antibacterin," "a polyvalent antibacterial agent," "the biochemical successor to vaccine," "natural antibody," "a therapeutic active immunizing agent." According to the Council's report of 1933 the complexity of the composition of Edwenil was indicated by the following excerpts from the advertising:

Edwenil is the result of fifteen years work representing an effort to produce natural immunity or a polyvalent natural antibody. It is a calcic protein compound consisting of three elements as follows:
CALCIUM in the form of the bicarbonate, which is apparently the form in which calcium is required for utilization by the immune body precursors.

A CALCIUM VEHICLE in the form of a nucleoprotein.
AN UNATTACHED GLOBULIN ELEMENT obtained from serum.
EDWENIL is a complex organic colloid formed by a linkage of some of the alkali denatured protein derivatives of normal serum and muscle in the presence of a normal saline containing calcium and magnesium salts.

More recent advertising contains the following statement concerning the composition of the preparation:

Edwenil is a deproteinized flocculus (protein 0.02 per cent) obtained by fractionation from an extract of beef muscle and normal horse serum. It is a potent polyvalent nontoxic lysinogen, or antibody stimulating agent which accelerates the mobilization of the potential defenses of the body against endotoxic bacteria.

The number of conditions for which it is recommended are legion and the claims made in the firm's advertising are most extravagant.

In 1935 two very instructive articles on nonspecific prophylactic therapy were published, prepared for the Council by Dr.

Cecil and Hektoen Following publication of these articles the Council inquired of Dr Cecil if he would have an investigation made to check some of the claims advanced by Spicer and Company for Edwenil Dr Cecil obtained the cooperation of Dr Stainsby and Miss Shultz The report of their work is reproduced herewith No beneficial effects were observed from the use of Edwenil¹ in animals infected with pneumococci or staphylococci The results of this study fail to confirm in any particular claims advanced by Spicer and Company for Edwenil

The Council reaffirmed its previous decision that Edwenil be declared unacceptable for inclusion in New and Nonofficial Remedies because it is an unscientific preparation of semisecret composition, marketed under a noninformative name with unwarranted therapeutic claims

In authorizing publication of the appended report, the Council expresses its appreciation to Drs Cecil and Stainsby and Miss Shultz for their cooperation

ANIMAL EXPERIMENTS WITH EDWENIL²

By WENDELL J STAINSBY, M D, AND
SELMA M SHULTZ, M A

Edwenil has been widely advertised as an effective therapeutic agent for controlling endotoxic infections in general and has been specifically recommended for a large number of diseases³

Spicer and Company, however, state in recent advertising⁶ that "Edwenil is a deproteinized flocculus (protein 0.02 per cent) obtained by fractionation from an extract of beef muscle and normal horse serum"

In the present study we have attempted to repeat the most promising animal experiments on which the wide claims for Edwenil have been based In doing this, careful attention has been paid to small details, such as the breed of animals, the amount and virulence of infecting organisms, and the size and number of the injections of Edwenil As a result of this, large doses of Edwenil, similar to those recommended for human beings, have been used in treating our animals

The strain of *Staphylococcus aureus* used in the study produced hemolysis on blood agar plates and was originally obtained from a patient infected with it The strain of pneumococcus type I used was a laboratory strain originally obtained from a patient suffering from lobar pneumonia

EFFECT OF EDWENIL IN PROTECTING INFECTED LABORATORY ANIMALS FROM DEATH

The first experiments were designed to determine whether Edwenil would protect albino mice infected with type I pneumococci As a preliminary test, it was desirable to know whether the drug itself is poisonous to these animals if injected either intraperitoneally or subcutaneously in large doses Five mice

TABLE 1—Effect of Edwenil on Mice Infected with *Pneumococcus Type I*

Control Animals			Treated Animals		
No of Organisms Injected	No of Animals	Result	No of Animals	Treatment with Edwenil	Result
50 000	5	Died in 48 hrs	1	Two 1 cc doses intraperitoneally during infection	Died in 30 hrs
			1	Two 1 cc doses intraperitoneally during infection	Died in 48 hrs
			3	Three 1 cc doses subcutaneously during infection	Died in 48 hrs
23 000	5	Died in 48 hrs	2	{One 0.25 cc dose subcutaneously before infection One 0.25 cc dose subcutaneously during infection	Died in 24 hrs
			3	{One 0.25 cc dose subcutaneously before infection Two 0.25 cc doses subcutaneously during infection	Died in 48 hrs
300	5	Died in 48 hrs	0	Three 0.25 cc doses subcutaneously during infection	Died in 48 hrs
100	0	Died in 48 hrs	3	Two 0.5 cc doses subcutaneously during infection	Died in 30 hrs
			2	Two 0.5 cc doses subcutaneously during infection	Died in 48 hrs
			2	{One 0.5 cc dose subcutaneously before infection One 0.5 cc dose subcutaneously during infection	Died in 30 hrs
			3	{One 0.5 cc dose subcutaneously before infection One 0.5 cc dose subcutaneously during infection	Died in 48 hrs
10	2	Died in 24 hrs	3	Two 0.5 cc doses subcutaneously during infection	Died in 30 hrs
	3	Died in 48 hrs	2	Two 0.5 cc doses subcutaneously during infection	Died in 48 hrs
			5	{One 0.5 cc dose subcutaneously before infection One 0.5 cc dose subcutaneously during infection	Died in 48 hrs

including furunculosis, acne tonsillitis and quinsy, leukorrhea drainage after operation, puerperal sepsis, bronchitis, bronchiectasis, bronchial asthma, lobar pneumonia, influenza, the common cold, rheumatoid arthritis, early osteo arthritis, sciatica, tuberculosis, rheumatic fever, measles, mumps, whooping cough scarlet fever, chronic pyelitis and cystitis and other febrile conditions These wide claims for Edwenil as a therapeutic agent are based on clinical observations and animal experimentation The clinical studies are totally unconvincing The animal studies, however, as reported in pamphlets⁴ circulated by the marketers, or in small almost inaccessible publications,⁵ indicate that Edwenil protects laboratory animals against lethal doses of certain pathogenic micro-organisms and increases the immunity of these animals to such an extent that it can be readily demonstrated by the usual laboratory procedures

The exact composition of Edwenil, as far as we have been able to determine, has not been made public The marketers,

were injected intraperitoneally with 1 cc of Edwenil All of them developed a chill immediately after the injection and appeared ill After approximately two hours' time, four of the five animals recovered and remained well The remaining animal died two hours after the injection Five other mice were injected with 0.5 cc of Edwenil subcutaneously These animals did not develop any symptoms and remained well From these experiments it is apparent that Edwenil is toxic to mice when injected intraperitoneally in the doses mentioned but not when injected with a smaller dose subcutaneously It seems quite probable that these toxic effects were due to the preservative in the preparation

With the foregoing experiment as a basis, the work outlined in table 1 was carried out Attention is called to the fact that in some of the experiments Edwenil was injected prior to infection as well as during infection in order that no question could arise as to whether the drug was administered early enough The minimal lethal dose of the strain of pneumococcus was determined and found to be from one to ten pairs of pneumococci The number of organisms injected varied from a dosage comparable to the one implied by the published experimental work down to the minimal lethal dose of our organisms No difference whatever could be observed between the treated and the control animals The mice injected with pneumococci whether treated with Edwenil or not died within forty-eight hours

1 The Edwenil used in this investigation was purchased on the open market

6 Undated pamphlet on Edwenil issued by Spicer and Company

In table 2 is presented an outline of experiments carried out on rabbits infected with either the strain of *Staphylococcus aureus* or the strain of pneumococcus. Care was taken to select rabbits of similar weights and ages for the treated and control groups. The organisms were injected intravenously in the amounts indicated after preliminary experiments had been completed to determine the lethal doses of the organisms. It should be noted that, with one group of animals, two separate injections of the pneumococcus were given. Edwenil was given in each case at daily intervals.

Altogether eighteen rabbits, nine of which were kept as controls, were infected with the pneumococcus. Two of the treated animals recovered, while three of the controls recovered. Of the animals that died, the average duration of life for the controls was four days, while for the treated animals it was eleven and a half days.

Twelve rabbits, six of which were kept as controls, were infected with *Staphylococcus aureus*. One of the controls and two of the treated animals recovered. Of those that died the average length of life for the controls was seventeen days and for the treated fifteen days.

were employed and the normal total white cell count was taken on three successive days. After the normal cell count was thus carefully determined, three of the rabbits were injected with 1 cc of Edwenil subcutaneously for three successive days while the other three were injected in a similar manner with physiologic solution of sodium chloride. Unnecessary trauma was eliminated. Total white cell counts were made each day on these animals while they were injected and on the day after the last injection. The results of this experiment appear in table 3, and it can be readily seen that leukocytosis did not occur in either the Edwenil treated group of animals or in the controls, which indicates that the leukocytosis occurring in the first experiments on healthy animals was due to some factor other than the Edwenil, probably the trauma. From these studies we conclude that Edwenil injected subcutaneously in healthy rabbits does not produce a leukocytosis.

EFFECTS OF EDWENIL ON THE TOTAL WHITE CELL COUNT OF INFECTED RABBITS

All the rabbits listed in table 2 were followed with total white cell counts until they died from infection or recovered.

TABLE 2—Effect of Edwenil on Infected Rabbits

	1	Died in 13 days	1	Three 1 cc doses subcutaneously during infection	Died in 8 days

Considerable experimental work in infecting guinea-pigs with strains of pneumococci was carried out. As is well known, the guinea-pig is particularly resistant to infection with pneumococci. Although several stock and freshly isolated strains were used, we were unable to obtain an organism of sufficient virulence for guinea-pigs to carry out experiments with this animal.

However, the experimental work with mice and rabbits, as reported by us, fails to provide any evidence that Edwenil protects these animals against death by infection with either pneumococci or staphylococci regardless of whether Edwenil was administered during infection or before infection as well.

EFFECT OF EDWENIL ON THE TOTAL WHITE CELL COUNT OF HEALTHY RABBITS

The normal white cell count was determined on nine healthy white rabbits and was found to average 8,156 cells. Each of these animals was injected with 1 cc of Edwenil subcutaneously for three, four or five successive days. During the period of the injection, venipunctures were made from the ear on several occasions for various other studies. On the day after the last injection of Edwenil, the total white cell count on these rabbits was found to average 15,233, a distinct increase. The question then arose as to whether the increased cell count was due to Edwenil or to the trauma occasioned by the injections and the venipunctures. To determine this point, six similar rabbits

from it. Altogether there were fifteen animals treated with Edwenil and fifteen controls, of which four recovered in the treated group and four in the controls. Counts were made daily for the first three or four days and thereafter at less frequent intervals. The intervals between counts on the control animals were similar to those on the treated animals. Altogether 183 total white cell determinations were made, and for brevity only the average counts are listed in table 4. From the table it is readily seen that a mild leukocytosis was present in the animals from the first day following infection, and that this became more marked after the eighth day. The white cell count on the animals infected with the staphylococcus was generally higher than that obtained on animals infected with the pneumococcus, but no differences were noted as between the Edwenil treated group and the controls. In addition, careful studies of the figures were made as regards the animals that recovered, as distinct from those that died, and regardless of how the figures were studied, no evidence was found that Edwenil increased the leukocytosis in rabbits infected with either the pneumococcus or the staphylococcus.

EFFECT OF EDWENIL ON THE DIFFERENTIAL WHITE CELL COUNT OF INFECTED RABBITS

The thirty rabbits listed in table 2 were also followed through out the course of their infection with differential white cell counts. For the first few days these counts were made daily.

and thereafter at somewhat longer intervals. All the smears for study were stained by Wright's technic and 100 cells were counted.

Although the rabbits infected with the staphylococcus developed a greater leukocytosis than those infected with the pneumococcus, the results of the differential counts were grouped together, as no appreciable relative increase of any type

Likewise when differential white cell counts of the rabbits that recovered from their infections were studied, no important differences were noted between the treated and the control animals. We are forced to conclude, therefore, that Edwenil did not influence in any way the differential cell count of rabbits infected with either the staphylococcus or the pneumococcus.

ADDITIONAL STUDIES CARRIED OUT WITH EDWENIL

The thirty rabbits outlined in table 2 were also followed during the course of their illness with blood cultures, agglutination tests and phagocytosis studies, and comparisons were made with similar tests carried out before the animals were infected. The results are as follows:

Blood Cultures—Blood cultures were carried out daily on each of the thirty animals for the first few days and at longer intervals thereafter. Some of the animals eliminated the organisms from the blood stream very rapidly, while others continued to have positive blood cultures either throughout the course of the disease or for several days after infection. No significant difference in this respect was noted between those treated with Edwenil and those kept as controls. Likewise, the number of organisms per cubic centimeter found in the blood cultures was similar for the treated and the untreated groups of animals.

Agglutination Studies—Agglutination tests between the rabbits' serum and the infective organism were carried out at frequent intervals throughout the course of the disease. While most of the rabbits infected with the pneumococcus did not live long enough to develop demonstrable agglutinins, two treated animals did develop them, one to a titer of 1:160 on the eighth day and one to a titer of 1:80 on the fifteenth day. Both of these animals later died from the infection. None of the controls in the group developed any demonstrable agglutinins.

Among the animals infected with the staphylococcus, two of the treated animals developed agglutinins, one to a titer of 1:40 on the forty-fourth day and the other to 1:160 on the eighth day. The first animal recovered and the second one died of the infection. In the control group that was infected with the staphylococcus one developed agglutinins to a titer of 1:40 on the forty-fourth day and the other to a titer of 1:40 on the eighth day. The first of these died of the infection while the second recovered.

From this study, no evidence was obtained that Edwenil increased the capacity of the animals to form agglutinins for the organisms with which they were infected.

Phagocytosis—Throughout the course of the disease, the thirty rabbits were followed frequently for the ability of their polymorphonuclear neutrophils to ingest the organisms with which the animals were infected. The method used was that

TABLE 3—Effect of Edwenil on Total White Blood Cell Count of Healthy Rabbits

Rabbits	Normal Counts	Time of White Cell Count After First Injection			
		24 Hrs	48 Hrs	3d Day	4th Day
102	10,200 13,300 13,500	12,700	10,800	12,100	10,700

different in the treated group than in the controls, but the differences are too small to be of any importance.

It is generally recognized that the subsidence of an acute infection manifests itself in the differential white cell count by a decrease in the immature polymorphonuclear cells and a marked, even if transitory, rise in the monocytes while convalescence is characterized by a normal immature polymorphonuclear count and a marked rise in lymphocytes. It would be expected, therefore, that if Edwenil favorably modified the course of the disease, some of the characteristics in the differential count which indicate recovery from infection would manifest themselves. In the summary of the differential white cell study presented in table 5, no important differences were noted between the rabbits treated with Edwenil and the controls.

advocated by Wright. Considerable variation was noted among the animals infected with the same organism. Phagocytosis was much more marked in the staphylococcus infected group than in the pneumococcus infected group, and in both groups of animals this capacity increased during the course of the disease. However, there was not the slightest evidence that Edwenil increased phagocytosis in any way.

COMMENT

Through pamphlets circulated by the marketers and small medical publications, wide claims have been made for Edwenil as a therapeutic agent based on experiments with infected laboratory animals. We have attempted to repeat the most promising of these experiments and have been unable to find any evidence whatever for the claim that Edwenil protects

infected laboratory animals from lethal doses of *Staphylococcus aureus* and of pneumococcus type I. In addition, our rabbits were studied intensively throughout the course of their disease by white cell counts, blood cultures, agglutination tests and studies on phagocytosis, and we were unable to find the slightest evidence that Edwenil increased the immunologic responses of these animals.

CONCLUSIONS

- 1 Studies of the effects of Edwenil on mice and rabbits infected with pneumococci or staphylococci were carried out.
- 2 The course of infection and mortality of these animals were not affected by injections of Edwenil.
- 3 During extensive immunologic studies on the infected animals, no beneficial effects were observed from the use of this substance.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

KINNEY'S YEAST EXTRACT CONTAINING VITAMIN B COMPLEX—A mixture of the water soluble extractive of dried brewers' yeast preserved by the addition of $\frac{1}{2}$ volume of glycerin-U S P and $\frac{1}{2}$ volume of simple syrup-U S P. It is biologically assayed to contain in each cubic centimeter 25 international units of vitamin B₁ and 10 Sherman-Borquin units of vitamin G.

Actions and Uses—Kinney's yeast extract containing vitamin B complex is proposed for prophylaxis and treatment of conditions arising from deficiency of the vitamin B complex in the diet (see general article *Vitamins and Vitamin Preparations for Prophylactic and Therapeutic Use*, N N R, 1937, p 446, under Vitamin B).

Dosage—Infants 2 cc ($\frac{1}{2}$ fluidrachm), adults 8 cc (2 fluidrachms) daily.

Manufactured by Scientific Sugars Co Indianapolis. No U S patent or trademark.

Kinney's vitamin B extract is prepared by extracting especially cultured dried brewers' yeast in an aqueous medium under proper conditions of pH control. The extract is concentrated, clarified and preserved with equal parts of glycerin U S P and simple syrup U S P.

The vitamin B₁ content is determined by comparison with the International Standard according to the Cowgill Pigeon Weight Maintenance Technic as outlined in *The Vitamin B Requirement of Man* by Cowgill chapter IV. At regular intervals samples are also compared with the International Standard according to the rat growth method of Sherman and Spohn as outlined in *The Vitamins* by Sherman and Smith edition 2 page 99.

The vitamin G content is determined by the Sherman Borquin Method as outlined in *The Vitamins* by Sherman and Smith edition 2 page 133.

The glycerin content is estimated according to the method described in *Methods of Analysis* A O A C 1930 page 302 chapter XVIII paragraph 55.

CORRECTION

Through error in the descriptions of several capsules and tablets of digitalis prepared by the McNeil Laboratories (*THE JOURNAL*, April 24, 1937, p 1410) the potency is given in "cat units." The products are standardized by the frog and the guinea-pig methods and not by the cat method. The description should therefore read:

DIGITALIS (See New and Nonofficial Remedies, 1937 p 180)

The following dosage forms have been accepted:

Tablets Digitalis Duo Test McNeil $\frac{1}{2}$ grain ($\frac{1}{2}$ U S P Digitalis unit) Dispensed in plain tablets.

Tablets Digitalis Duo Test McNeil 1 grain ($\frac{1}{2}$ U S P Digitalis unit) Dispensed in plain and enteric coated tablets. The enteric coated tablets are first coated with a wax salol mixture and then sugar coated green.

Tablets Digitalis Duo Test McNeil $1\frac{1}{2}$ grains (1 U S P Digitalis unit) Dispensed in plain and enteric coated tablets. The enteric coated tablets are first coated with a wax salol mixture and then sugar coated green.

Capsules Digitalis Duo-Test McNeil $1\frac{1}{2}$ grains (1 U S P Digitalis unit) Dispensed in black capsules.

Prepared by the McNeil Laboratories Inc Philadelphia

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
FRANKLIN C BING, Secretary

FLEISCHMANN'S YEAST NOT ELIGIBLE FOR THE LIST OF ACCEPTED FOODS

Fleischmann's Yeast is distributed by Standard Brands Incorporated, New York. The fresh, compressed yeast is sold in small packages called "cakes." Each cake, weighing about 125 Gm, is wrapped in tin foil. The product consists essentially of a viable strain of yeast and is used for various culinary purposes. In 1922 E M Bailey, Helen C Cannon and H J Fisher at the Connecticut Agricultural Experimental Station reported the approximate composition of the product to be moisture 65.4 per cent, ash 2.83 per cent, total nitrogen 1.15 per cent, water soluble nitrogen 0.37 per cent, water insoluble nitrogen 0.87 per cent, starch present. The average weight of the fresh cakes examined was 138 Gm. The Connecticut investigators at that time reported Fleischmann's Yeast to be a poor source of vitamin B (complex) as compared with dried brewers' yeast even though allowance was made for the moisture content of the fresh product. It is now generally recognized that the vitamin B content of yeast depends to a large extent on the substrate on which the yeast cells are cultured and there is no doubt that Fleischmann's Yeast could be a better source of vitamins B₁ and G in 1937 than it was in 1922.

Label—If one examines the label of the product in search of more recent information about the vitamin content, there is little information to be found. The label on the small cakes states merely that the product supplies vitamins A, B, D and G and that cereal or tapioca flour and primary vitamin A are added. The label bears the additional information, in red letters, to "Eat 3 cakes daily—before meals."

The Council on Foods has classed fresh compressed yeast among the so called special purpose foods. The vitamin B₁ and vitamin G potency of acceptable brands of yeast must be determined by biologic assay and the number of units of each vitamin that one could expect to find in the product is required to be declared prominently on the label. One looks in vain for any label statement regarding the number of vitamin units that could reasonably be expected to be derived from Fleischmann's Yeast. It is stated only that the product supplies vitamins A, B, D and G. There are a number of other foods of which it could be stated truthfully that they supply these same vitamins although one would have to know the amount present before deciding whether the quantity is sufficient to warrant mention in advertising. But quantitative information is lacking on the label of Fleischmann's Yeast. The product could be extremely variable and still be in accord with the present vague label declaration. There is lacking the assurance that a truly informative label might give that the potency of the product will be maintained irrespective of fluctuations in the cost of the primary vitamin A which is added or of the food substances on which the yeast cells are grown. Indeed, the label does not even indicate how much "filler" in the form of starch or cereal is added. Are small amounts of other ingredients added? How much vitamin D is present, and what is its source? These questions are not answered on the label.

DISCUSSION OF CLAIMS

Although the label of Fleischmann's Yeast bears little specific information, the advertising copy claims a great deal. The newer trend in advertising of this culinary product appears to be along nutritional lines. Claims are made for each of the vitamins and for the mixture said to be present in Fleischmann's Yeast. Comments on advertising that has appeared in recent numbers of popular magazines and newspapers may be divided for convenience into a discussion of the claims made for each of the vitamins and for the product as a whole.

Vitamin A—Advertising emphasis has been placed on the supposed relationship between vitamin A and the frequency of

colds Illustrations of a man in the act of sneezing are accompanied by the suggestion that the reader should let Fleischmann's Yeast help increase his daily supply of vitamin A and so help decrease the frequency of colds The Cooperative Committee on Vitamins reviewed the evidence available in 1936 and said

It [vitamin A] certainly has not been shown to be specific in the prevention of colds influenza and such infections nor has it been demonstrated that the ingestion of vitamin A far in excess of that necessary for normal body function and readily obtained from a properly selected diet is an aid in preventing various types of infection

It is misleading to the public, therefore to assert or imply that products containing vitamin A will aid in the prevention of colds

Vitamin B—If you have a "sagging stomach" poor digestion and "sluggish intestines" you are urged to add Fleischmann's Yeast to your regular diet to increase your supply of vitamin B There is no adequate basis for such statements and the Council does not recognize these claims

Vitamin D—Reference is made in some recent advertising to the work that has been done on the role of vitamin D in tooth formation and in the maintenance of normal tooth structure The Council takes no objection to such statements of fact provided the claim is not made that adequate vitamin D intake will insure normal tooth structure or will prevent dental caries

Vitamin G—One particularly objectionable claim that has appeared in recent advertising is concerned with statements made for vitamin G One illustration shows a thin round-shouldered, undernourished child with the caption "Too little vitamin G means poor growth" For contrast the picture of a taller, apparently well nourished child, standing erect and looking alert is presented with the heading "Diet ample in vitamin G" The explanatory text states that Fleischmann's Yeast is very rich in vitamin G, that children from 5 to 12 years of age can be given one to two cakes daily The obvious implication is that a thin, underweight child—perhaps one reported by a school physician as "malnourished," perhaps a tuberculous child not seen by a physician—can be made well and strong by eating Fleischmann's Yeast It is the opinion of the Council that a poorly nourished child requires the attention of a family doctor rather than the dietary advice of the Fleischmann Yeast Company

Claims for the Mixture of Substances That Comprise Fleischmann's Yeast—Dietary advice of dubious accuracy appears to be an important feature of some of the current advertising for Fleischmann's Yeast An advertisement which appeared in a recent number of a national woman's magazine has for a heading "You can't count on meals alone for vitamins you need" Another advertisement has for a heading "Many diets short in vitamins" The thesis that one cannot depend on meals alone for vitamins depends on the foods chosen A proper selection of the diet will insure a sufficient intake of all the vitamins that an adult requires Infants and small children need some vitamin D other than can be supplied in ordinary foods and there is available a variety of acceptable preparations which declare the unitage of vitamin D and thus enable the required dosage for the individual infant or child to be prescribed

Fleischmann's Yeast is said to be "the only natural food that furnishes such an abundant supply of all four of these vitamins (A, B, D and G) at once" The meaning of the expression "natural food" is certainly not clear when applied as it is here to a mixture of yeast cells treated to give a vitamin D activity, cereal or tapioca flour and carotene

Illustrations of athletes are presented with the comment that their sturdy build shows they are abundantly supplied with "the four important health-building vitamins A, B, D and G" The use of the phrase "the four important health-building vitamins" would seem to imply that nothing else need be considered in the diet No mention is made of vitamin C nor is any mention made of calories or protein or other dietary essentials or the countless other factors involved in the maintenance of good health in addition to the four vitamins A, B, D and G

For some time Fleischmann's Yeast has been promoted with the claim that its ingestion would sweep out poisons from the blood

Eat it regularly, says Dr. R. E. Lee, well known physician and Fleischmann's Yeast will help clear up adolescent pimples

Pimples put an end to popularity for many girls and boys after the start of adolescence—from about 13 to 25 or even longer Fleischmann's Fresh Yeast is helpful in clearing up a pimply skin because it clears these skin irritants out of the blood Eat three cakes every day—one or two cakes cannot do the work

As far as the Council on Foods is aware there is no adequate evidence in support of the claim that eating Fleischmann's Yeast will "help clear up adolescent pimples," and the Council does not recognize any therapeutic claim of this nature for any brand of fresh yeast

SUMMARY

There are now available on the open market a number of fresh and dehydrated yeast preparations which are advertised conservatively with claims based on the actual composition of the product Fleischmann's Yeast in contrast is sold with grossly exaggerated or unwarranted claims The Council on Foods voted, therefore, that Fleischmann's Fresh Compressed Yeast be declared ineligible for the list of accepted foods because it is inadequately labeled and is promoted with exaggerated or misleading claims

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C. BING, Secretary

CHOC-LADE DAIRY DRINK POWDER

Manufacturer—Siren Mills Corporation, Chicago

Description—Powdered mixture of cocoa starch-free powdered cane sugar, vegetable emulsifying agent, salt and vanilla flavoring

Manufacture—The ingredients in formula proportions are mechanically mixed for forty-five minutes and packaged

Analysis (submitted by manufacturer)—Moisture 0.0%, ash 2.1%, fat 9.2%, protein (N \times 6.25) 9.2%, sucrose 27.9%, crude fiber, 2.6%, carbohydrates other than crude fiber (by difference) 76.9%, caffeine and theobromine 0.94%

Calories—4.27 per gram, 121 per ounce

Claims of Manufacturer—For preparation of special Choc-Lade beverages in accordance with specific license contracts and conditions of preparation

FORT WESTERN BRAND HAWAIIAN PINE-APPLE, SLICED, CRUSHED AND DAINTY SECTIONS

Distributor—Holmes-Swift Company, Augusta, Maine

Packer—Hawaiian Pineapple Company, San Francisco

Description—Canned pineapple packed in concentrated pineapple juice with added sucrose, the same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, p. 1106, April 29, 1933, p. 1338, and April 4, 1936, p. 1166)

COLONIAL FLOUR, PHOSPHATE ADDED

Distributor—C. B. Ragland Company, Nashville, Tenn.

Manufacturer—Bliss Milling Company, Seymour, Ind.

Description—An "all purpose" "short patent" flour milled from soft wheat, bleached, phosphate added, the same as Colonial Flour, Phosphate Added (THE JOURNAL, May 22, 1937, p. 1801)

FI-NA-ST BRAND TOMATO JUICE

Distributor—First National Stores, Inc., Boston

Packer—Curtice Brothers Company, Inc., Rochester, N. Y.

Description—Canned tomato juice seasoned with salt retaining in high degree the natural vitamins The same as Blue Label Tomato Juice (THE JOURNAL, April 24, 1937, p. 1410)

FURUNCLE OF THE FACE

The problem of proper therapy of the facial furuncle is apparently far from settled. Recent contributions to the subject resort to the time honored custom of proving the case by statistics. Among the fallacies of the statistical method, none is more apparent than the comparing of results obtained in treatment by dissimilar groups. Ayres, Anderson and Foster¹ report the results of a questionnaire sent to 250 dermatologists and to an equal number of surgeons. Dermatologists, it seems, tend toward conservatism in the treatment of carbuncles, whereas surgeons are more inclined to use radical procedures. The majority of surgeons employ crucial incisions or cautery excisions of carbuncles, whereas the majority of dermatologists employ conservative methods, including x-rays, vaccines, bacteriophage and topical applications. The mortality from carbuncles is low in both groups, but it is more than three times as great under surgical as under dermatologic treatment. Cases of infection of the face coming to the surgical clinic, however, are usually of a more severe type than those seen by the dermatologist.

Most infections about the lip and face heal spontaneously under any type of treatment. There is, however, the potential danger of grave and even fatal complications. Infections of that portion of the face which includes the lips, nose, chin, lids and forehead are regarded as most likely to give rise to grave complications. Among these, furuncles of the upper lips and the nares give the highest percentage of fatal complications. The common etiology of a furuncle is the combination of lack of cleanliness with irritation and the ever present staphylococcus. The spreading potentialities of the facial carbuncle are due to the anatomic and physiologic peculiarities of the soft tissues of the face. The skin of the central portion of the face differs functionally from the rest of the skin in that it participates in facial mimicry. The particular anatomic

arrangement consists in the muscles of expression taking their origin from the bones of the face and inserting directly into the deep portions of the skin. The facile play of these muscles is further aided by the fact that they are not enclosed within stiff fascial sheaths. They are, instead, surrounded by loose subcutaneous tissue. The absence of fascial partitions and the almost constant movement of the overlying skin are potent factors in aiding the spread of an infection by continuity. Underlying these muscles of expression and mastication is a rich network of veins, likewise surrounded by loose connective tissue. These veins, according to Collier and Yglesias,² present certain structural anomalies such as the absence of valves and the relative rigidity of their walls. The inflammatory process involves the veins by compression and formation within them of septic thrombi. The thrombophlebitic process of the central portion of the face can extend in two directions: (1) by way of the nasal veins, the superior labial, the angular vein and its anastomosis with the superior and inferior ophthalmic veins into the cavernous sinus or (2) by way of the anterior facial vein, the common facial and the internal jugular vein into the general circulation. The resulting cavernous sinus thrombosis, meningitis, brain abscess or septicopyemia are almost always fatal.

Consensus of dermatologists and surgeons alike favors the conservative plan of treatment of at least the early and the benign infections of the face. Infectious lesions of the face, particularly those about the upper lip and the nose, should not be traumatized. The temptation to squeeze a pimple or to destroy it by a chemical substance may easily lead to the spread of infection, first by continuity and next by way of the blood stream. The principles underlying the conservative treatment may be summarized in (1) rest and (2) stimulation of the local and general defense mechanisms. The patient is put to bed in a hospital and speech is interdicted. He is fed fluids, preferably by gavage, so as to eliminate the process of chewing. Appropriate sedatives, analgesics and hypnotics are indicated to control the pain and insure rest and sleep. Specific immunization is best accomplished by intravenous administration of autogenous vaccines. Neither the method of autohemotherapy advocated by Bier nor that of Laeven of injecting blood into the healthy tissue about the carbuncle has gained much favor in this country. Roentgen irradiation appears to be capable of aborting many of the early infections and of promoting the breaking down and localization of the more advanced lesions. The roentgen rays are not in themselves bactericidal. The favorable action is believed to be due to the breaking down of certain radio sensitive cells and the consequent liberation of powerful antitoxic substances. Hot, wet applications, the old fashioned hot flaxseed poultices, tend to relieve pain

¹ Ayres Samuel Jr, Anderson N P and Foster P D. *Dermatologic versus Surgical Treatment of Carbuncles and Furuncles*. J A M A 108 858 (March 13) 1937

² Collier F A and Yglesias Luis. *Infections of the Lip and Face*. Surg Gynec & Obst 60 277 (Feb 15) 1935

and to limit the infection. The tendency is not to incise the early lesions but to wait until the infection "comes to a head", in other words, until the pus comes to the surface of the skin, or until there is fluctuation. This is perhaps the most widely accepted plan despite the few objectors. Foote,³ for example, does not consider the furuncle of the face as being different from that in any other location. He insists that a prompt incision offers the best chance to check the infection locally and to limit its spread.

In a fortunately small percentage of the cases, infection is fulminant from the very beginning or may take on a grave form after an apparently mild initial course. It is manifested by advancing edema, increasing induration about the furuncle, tenderness along the dilated larger venous trunks, increase in pain, fever and signs of general intoxication. Among the many surgical interventions advocated for the treatment of these complications may be mentioned crucial incisions with the cautery knife and undercutting of the edges, wide excision of the carbuncle with an electrocautery knife, ligation of the angular vein to prevent extension of the septic thrombosis into the cavernous sinus and, finally, the exposure and evacuation of the contents of the cavernous sinus in the presence of symptoms suggesting its development. In view of the rich venous anastomosis, ligation of the angular vein appears to be of doubtful value. Lexer advises ligation of the internal jugular vein as the first step in the treatment of a malignant infection of the lower lip and the chin. The prophylactic injunction not to squeeze or prick a pimple, no matter how small, together with prompt institution of the conservative treatment, will probably limit the number of grave cases to a minimum.

IRON METABOLISM IN EARLY INFANCY

Iron is essential for the growth and development of the human infant. At birth, considerable amounts of iron are stored in the liver¹ and to a lesser extent in other tissues, to insure an adequate supply of this element for the formation of new hemoglobin and body tissues during the period of nursing. If a sufficient store of iron is lacking, severe anemia develops far in excess of the "physiologic anemia" usually found during the first year of life. Such a condition is sometimes observed in premature infants in whom the amount of reserve iron is deficient because of the shortened period of access to the maternal supply of iron, and in full term infants whose reserve supply of iron is low because of a deficiency of this element in the maternal organism during gestation.

The liver has been generally regarded, heretofore as the chief site for the storage of iron during the fetal period. Recently, however, evidence has been pro-

duced indicating that this is not the case.² A study of data in the literature on the nonhemoglobin iron content of the liver of the human infant at birth shows that the amount of this element stored is not as large as might be expected, the quantity varying from a negligible trace, if the diet of the mother has been low in iron, to a maximum of possibly 60 mg. By 6 months of age the amount of reserve iron in the liver appears to be reduced to approximately 15 mg, thus indicating that 45 mg has been utilized. However, the average amount of new hemoglobin formed during this period would require by itself, exclusive of the iron needed for muscle and tissue growth, at least 80 mg. The amount of iron stored in other tissues could not meet this need and it could not be supplied from an exclusive milk diet. Indeed, balance studies made on infants during the first two months of life² show that there is a negative iron balance, the total average excretion of the element exceeding by 50 to 75 mg the dietary intake. During the next four months the infant remains practically in iron equilibrium.³ Thus it is necessary to account for at least 130 to 155 mg of iron needed during the first six months of life, and of this amount no more than 45 mg is supplied by the liver.

The question appears to be reasonably answered by hematologic studies made on infants during early infancy.² The hemoglobin content of the blood of the human infant at birth is exceedingly high, averaging from 22 to 23 Gm per hundred cubic centimeters, and during the first few weeks of life there is a rapid decrease in the value, a 'physiologic anemia' developing. A level of from 10 to 12 Gm of hemoglobin per hundred cubic centimeters of blood is usually observed by the sixth to the eighth week after birth. The amount of iron released by the destruction of hemoglobin during this period has been calculated and has been found to be approximately 250 to 300 mg. Since, as was pointed out, only 50 to 75 mg of "extra" iron is lost in the excreta during this period, it is obvious that the iron from the destroyed hemoglobin is efficiently conserved and that this iron, rather than stored liver iron, forms the major reserve supply of this element in the human infant.

Although the conservation of iron from excess hemoglobin destroyed during the first few weeks of life is relatively efficient, the fact that the average total loss of iron, in excess of the intake, is from 50 to 75 mg during the first two months of life cannot be disregarded. In the cases of infants fed cow's milk, who frequently show a negative iron balance during the entire first six months of life, infants whose mother's diet has been deficient in iron during gestation, and premature infants, it would seem desirable to supply some additional source of dietary iron at an early age preferably well before the infant is 6 months old.

Current Comment

THE TRUTH ABOUT EDWENIL

For several years THE JOURNAL has had many inquiries about Edwenil. The almost unlimited claims made in advertising broadcast by the distributor, Spicer & Co., aroused the curiosity of physicians. In 1933 the Council on Pharmacy and Chemistry rejected the product but has recently given it reconsideration. The report of the Council's latest consideration appears on page 272 of this issue. The reaffirmation of the Council's rejection is sustained by the excellent paper of Dr Stainsby and his associate, which is appended to its report. Based as it is on a complete and scientifically conducted refutation of the bulk of evidence offered for Edwenil, the Stainsby report reduces the propaganda of the distributor to the level of quackery at worst or of extreme overoptimism at best. It is possible definitely to class most of the claims for Edwenil as false, unwarranted or unsupported. The authors were unable to find the slightest evidence that Edwenil increased the immunologic response of the animals used in their studies.

IMPROVED POLLEN ANTIGENS

Relatively inert aqueous pollen extracts can be changed to highly efficient vaccines by alcohol precipitation, according to the unconventional conclusion reported by Manteufel and Kuhne¹ of the Hygienic Institute, Dusseldorf. From the previous failures to sensitize or immunize guinea-pigs or rabbits by the use of native aqueous pollen extracts van Leeuwen and others² concluded that pollen allergy is not a clinical phenomenon similar to experimental anaphylaxis in laboratory animals. Recently, however, Haag,³ of Dr Manteufel's laboratory, showed that an occasional guinea-pig can be actively sensitized to native aqueous pollen extracts if sufficiently large doses and sufficiently long incubation periods are adopted. Haag found that this borderline antigenicity of native pollen extracts could not be increased by concentration of the aqueous extract by partial evaporation. These immunologists also studied the effects of concentration (or fractionation) of aqueous extract by alcohol precipitation. The precipitate thus formed was taken up as a colloidal suspension in sodium chloride solution. The suspension contained no macroscopically visible particles. Repeated intraperitoneal injections of 0.5 cc of the resulting 0.2 per cent precipitate suspension invariably sensitized guinea-pigs to homologous pollens. When reinjected eight weeks later with homologous antigens, approximately a third of the animals reacted with typical fatal anaphylaxis. The remaining two thirds showed from mild to severe typical nonfatal shock. Control groups of guinea-pigs injected with native (or undenatured) aqueous pollen extracts were not demonstrably sensitized. The authors found that the incubation period for sensitization to precipitated antigen is

approximately two months. Maximum sensitivity was not reached till the sixth to the eighth month. In their hands sensitivity thus conferred was not serologically transferable and all attempts to produce classic passive anaphylaxis gave negative results. Young born to mothers sensitized from four to five months previously, however, were invariably highly hypersensitive. The authors predict that similar methods of alcoholic fractionation (or purification) will become applicable to the preparation of some bacterial vaccines.

TYPHOID LEUKOCIDIN

According to Dennis and Senekjian¹ of the department of bacteriology at the American University of Beirut School of Medicine, Lebanon, the typhoid bacillus forms or secretes a powerful enzymic factor having a selective toxic action on neutrophilic granulocytes. In their opinion this newly discovered leukocidin may be responsible for the characteristic leukopenia in typhoid fevers, for depletion of myelopoietic elements in the bone marrow and for the absence of cellular infiltration about foci of typhoid infection. To demonstrate leukocidic activity of typhoid bacilli the Beirut investigators mixed heparinized rabbit and nonimmune human blood with an equal volume of varying dilutions of the filtrate from twenty-four hour veal infusion broth cultures of *Eberthella typhi* and incubated the resulting mixtures at 37°C in a rotating box for sixty minutes. Toxic or lytic action was demonstrated in the incubated mixtures by routine differential blood counts. Lytic action was deduced from observed reductions in the total number of leukocytes per cubic millimeter and by visible degeneration changes in nonlysed cells. When a potent typhoid filtrate was tested a 50 per cent reduction in the total leukocyte count was usually noted by the end of sixty minutes, as compared with control mixtures of veal infusion broth and human or rabbit blood. The neutrophilic granulocyte was the only cell type thus reduced. Differential counts showed neutrophilic lysis in dilutions as high as 1:1,000 of typhoid filtrate, with destructive activity in dilutions as high as 1:10,000. The typhoid leukocidin is reduced 50 per cent in potency by heating to 85 per cent for sixty minutes and completely inactivated by heating to 100°C for two hours. The active principle readily passes the Berkefeld, Chamberland and Sertz filters. The active lytic principle may be precipitated from a typhoid filtrate by the addition of three volumes of 95 per cent alcohol in the cold. This is the conventional method for precipitation and concentration of streptococcal fibrinolysin and numerous other bacterial enzymes. The dried precipitate thus obtained can be kept for at least a year without appreciable loss of potency. The lytic factor is neutralized *in vitro* by specific antityphoid sera. A good antiserum may contain as many as 50,000 arbitrary neutralizing units per cubic centimeter. The authors found no qualitative or quantitative differences between the leukolytic activity of different strains of typhoid bacilli, filtrates from paratyphoid A and B, however, showed relatively little leukocidal activity.

Society News—Dr Charles H de Turck Shivers Atlantic City, addressed the Cumberland County Medical Society, Bridgeton, June 15, on diseases of the urinary tract.—Dr Emanuel D Friedman, New York, addressed the Bergen County Medical Society, Hackensack, June 15, on "Trauma and the Nervous System."—Dr John A Brooke, Philadelphia, addressed the Cape May County Medical Society, Ocean City, May 20, on "Fracture of the Neck of the Femur."

NEW YORK

Dr Cunningham Appointed Dean at Albany—Dr Robert Sydney Cunningham, professor of anatomy at Vanderbilt University School of Medicine, Nashville, Tenn, has been appointed dean of Albany Medical College, Albany, to succeed Dr Thomas Ordway. Dr Cunningham is a native of South Carolina and graduated from Johns Hopkins University School of Medicine, Baltimore, in 1915. He was a member of the faculty of Johns Hopkins from 1915 to 1925, when he went to Vanderbilt as professor of anatomy. He will also hold a professorship of anatomy at Albany.

Three Outbreaks of Food Poisoning—Three outbreaks of illness caused by contaminated food have been traced to a bakery in Troy since April 1936. At that time six cases occurred in persons who had eaten chocolate eclairs. In May of this year there were six cases of gastro enteric disturbance in Troy and five in Rensselaer, all attributed to eating cream pies from this bakery. The third outbreak comprised twelve cases in Troy in June, attributed to the eating of strawberry cream pie. Investigation disclosed that the cream filled pastries supplied by the bakery in question were not subjected to refrigeration. The plant was found to be in satisfactory sanitary condition and no evidence was found of illness or skin lesions among the employees. The laboratory investigation had not been completed at the time of the report in *Health News*.

New York City

City Hospitals on Eight Hour Day—The entire work force of the Department of Hospitals, except administrative officers, physicians and superintendents of nurses, was placed on an eight hour day July 1. The new arrangement changes the hours for nurses, attendants, cooks, household and kitchen helpers and ambulance drivers, some employees have been working on this schedule for some time. The change is made possible by an appropriation of \$1,500,000 by the board of estimate. The department will require 2,793 additional personnel, including 1,281 graduate nurses and 349 hospital attendants or nurses' aids.

Knickerbocker Hospital Seventy-Five Years Old—Knickerbocker Hospital celebrated the seventy-fifth anniversary of its founding at a luncheon at the Hotel Astor May 20, with Nicholas Murray Butler, Ph D, president of Columbia University, as the principal speaker. Congratulatory messages from President Roosevelt and Governor Lehman were read. The hospital had its beginning in a tent set up by a young physician in 1862 to care for wounded and sick Union soldiers home from the Civil War. In May of that year the number of patients had grown so much that the Manhattan Dispensary was founded to care for them. The dispensary grew into a general hospital, known for many years as the J. Hood Wright Memorial Hospital and since 1913 as Knickerbocker Hospital according to an account in the *New York Times*. It now has 175 beds.

NORTH CAROLINA

University Changes—Evan W. McChesney, Ph D, associate professor of biological chemistry, University of North Carolina School of Medicine, Chapel Hill, recently resigned to join the faculty of Baylor University College of Medicine, Dallas, Texas, with the same title. At a meeting of the Columbus Academy of Medicine, June 14, the speakers were Drs. Earl H. Baxter and Leslie L. Bigelow on the medical and surgical aspects respectively, of abdominal pain in childhood, and Dr. Ralph I. Fried, on treatment of congenital syphilis.

PENNSYLVANIA

Society News—Dr. Joseph H. Barach, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, July 8, on "Clinical Application of Protamine Insulin." Speakers at a meeting of the Lycoming County Medical Society, Williamsport, July 9 were Drs. John Moore Campbell Jr., Harrisburg, on "The New Tuberculosis Program of the State Department of Health," Reynold M. Grieco, "Newer Method of Diagnosis and Treatment of Pathologic Conditions of the Rectum," and Lloyd E. Wurster, "Deep Roentgen Ther-

apy in Carcinoma of the Prostate and Its Metastasis."—Drs. Edgar S. Everhart and John R. Heller Jr. of the U. S. Public Health Service, and Albert F. Doyle, all associated with the state department of health, Harrisburg, presented a symposium on syphilis at a meeting of the Mifflin County Medical Society, Lewistown, June 3, and of the Blair County Medical Society, Altoona, June 22.

RHODE ISLAND

Society News—At a meeting of the Providence Medical Association, June 7, Drs. Hugh E. Kiene and William M. Muncy spoke on "Survey of Seven Years Treatment at the Chapin Hospital" and "Eye Manifestations for Trypanosomid Reactions" respectively. Dr. Charles L. Farrell, Pawtucket, addressed the Washington County Medical Society, Westerly, July 14, on "State Medicine."

Personal—Dr. Ernest A. Charon, Manville, has been appointed health officer of Lincoln, succeeding the late Dr. Harry A. Manchester. Dr. Francis V. Corrigan, Providence, assistant chief of the bureau of child hygiene in the state department of health for the past sixteen months, has been appointed chief succeeding Dr. Marion L. A. Gleason, who retired. Dr. Gleason has served since 1923. Dr. Michael J. O'Neil, Providence, has been appointed medical director of the state unemployment relief commission. He succeeds Dr. Henry J. Hoye.

SOUTH DAKOTA

Food Handlers to Be Examined—A plan for examination of food handlers in Sioux Falls was recently instituted by the city health officer. Examinations are to be made every six months and are voluntary on the part of proprietors. Restaurants, groceries and meat markets that cooperate will receive cards certifying that all food handlers have certificates of health.

TENNESSEE

Tennessee Valley Association Meeting—Dr. Elbert G. Wood, Knoxville, was chosen president-elect of the Tennessee Valley Medical Association at its meeting in Knoxville, June 23-25. Vice presidents elected are Drs. Ancil A. Richardson, Williamsburg, Ky.; Glenn T. Foust, Norton, Va.; and James Frank Pate, Canton, N. C. Dr. Jesse C. Hill, Knoxville, was reelected secretary. Dr. Edward A. Gwynes, Knoxville, was installed as president. Among the speakers were Drs. George W. Crile, Cleveland; Hugh H. Young, Baltimore; Virgil E. Simpson, Louisville, Ky.; Willis C. Campbell, Memphis; Francis T. Hunter, Boston; James E. Paullin, Atlanta, Ga.; and Leon J. Menville, New Orleans.

TEXAS

Hospital Head Appointed—Dr. Edgar M. Dunstan, medical director of Baylor Hospital, Dallas, was recently appointed superintendent of the Dallas city and county hospital system to succeed Dr. James H. Stephenson, who became superintendent of the Jefferson Davis Hospital, Houston. Dr. Dunstan will have charge of Parkland General Hospital and the Woodlawn tuberculosis unit in Dallas and the Convalescent Hospital at Hutchins.

Premedical Fraternity Dinner—The Texas Alpha chapter of Alpha Epsilon Delta, honorary premedical fraternity, recently gave a dinner at the University of Texas, Austin, for all Texas premedical students. More than 300 students and faculty members from eight Texas colleges and universities were present. Harry Y. Benedict, LL.D., president of the University of Texas, Austin, was toastmaster and guest speakers included Drs. Calvin R. Hanna, Dallas, president of the State Medical Association of Texas; Walter H. Moursund, dean, Baylor University College of Medicine, Dallas; and Edward H. Carv, Dallas, past president of the American Medical Association.

UTAH

Commonwealth Fund to Build Hospital—The Commonwealth Fund of New York has awarded to Provo the tenth of its hospitals for rural areas, and will contribute \$200,000 while the city will be required to raise about \$75,000 for the hospital.

WASHINGTON

Personal—Dr. John W. Adams, Waterville, has resigned as health officer of Douglas County. Dr. John N. Alley, superintendent of Tacoma Hospital, Tacoma, operated by the U. S. Department of the Interior, has retired from that position and has been appointed to the staff of the Eastern State Hospital, Medical Lake. Dr. Lawrence E. C. Joers, Tacoma, has been appointed health officer of Pierce County to succeed Dr. Hinton D. Jonez.

Rabies Quarantine in King County—The increase of rabies in recent months led the state director of agriculture to establish quarantine regulations for dogs in King County, according to *Northwest Medicine*. Regulations require that dogs be vaccinated annually with rabies vaccine or else be confined on their owners' premises. Vaccinated dogs may be allowed freedom twenty-one days after their vaccination and they must wear metal tags to indicate to enforcement officers that they have been immunized. Dogs being removed from the county must be accompanied by certificates of vaccination. Any dog that has been bitten by a rabid dog must have the Pasteur treatment or be destroyed. If he has the treatment he must be kept in quarantine for ninety days. The quarantine is to remain in effect until June 30, 1939.

WEST VIRGINIA

Refresher Courses—The state health department in cooperation with the West Virginia State Medical Association has provided refresher courses in obstetrics, pediatrics and venereal diseases in fifteen towns of the state. The series began July 12 and one meeting will be held in each location once a week for seven weeks. Drs. William J. Dieckmann and Morris Edward Davis, Chicago, and Everett D. Plass, Iowa City, are giving the lectures on obstetrics; Drs. Edwards A. Park, Baltimore, and George M. Lyon, Huntington, those on pediatrics. The lecturers on venereal disease had not been selected at the time of the announcement.

WISCONSIN

Personal—Dr. Harold H. Fechtner, Wausau, has resigned as director of the Marathon County health unit established in 1936, to resume private practice.—Dr. George Van Ingen Brown, Milwaukee, professor of plastic surgery, University of Wisconsin Medical School, Madison, has retired.

Bardeen Lecture—The Charles R. Bardeen Memorial Lecture honoring the late dean of the University of Wisconsin Medical School, Madison, was presented May 24 at the university under the auspices of the Phi Chi fraternity. Dr. Jacob Arnold, Bergen, Rochester, Minn., gave the lecture on "Recent Advances in Studies on Intestinal Disorders in Europe and America. Personal Observations."

PHILIPPINE ISLANDS

Hospital News—The late Dr. Gregorio Singian left 350 mg. of radium, valued at \$100,000, to the San Juan de Dios Hospital, Manila.—Dr. Gervasio Santos Cuyugan, for twelve years director of the Tayabas Provincial Hospital, has retired to enter private practice in Manila.

GENERAL

Examinations in Pediatrics—The American Board of Pediatrics will hold fall examinations on the following dates:

- Chicago, Sunday, October 17, following the meeting of region III of the American Academy of Pediatrics.
- Los Angeles, Sunday, November 7, following the meeting of region IV.
- Boston, Sunday, November 14, following the meeting of region I.
- New Orleans, Tuesday, November 30, following the joint meeting of region III with the Southern Medical Association.

Obstetrics Board Examinations—The American Board of Obstetrics and Gynecology announces that the next written examination and review of case histories of group B applicants will be held in various cities in the United States and Canada, November 6. The next general examination for all candidates will be in San Francisco, June 13-14, 1938, immediately before the meeting of the American Medical Association. Application blanks and booklets of information may be obtained from Dr. Paul Titus, secretary of the board, 1015 Highland Building, Pittsburgh. Applications must be filed not later than sixty days prior to the examination dates.

Society News—Dr. Edgar G. Ballenger, Atlanta, Ga., was chosen president-elect of the American Urological Association at its annual meeting in Minneapolis, June 30, and Dr. David W. MacKenzie, Montreal, was installed as president. Dr. Clyde L. Deming, New Haven, was reelected secretary.—Dr. Alphonse McMahon, St. Louis, was elected president of the American Therapeutic Society at the annual meeting in Atlantic City, in June.—The fifth annual meeting of the Western Orthopedic Association will be held in Seattle, July 28-30, with headquarters at the Washington Athletic Club.—The third annual meeting of the Mississippi Valley Medical Society will be held in Quincy, Ill., September 29-October 1.

Dr. Young Awarded Medal—Dr. Hugh H. Young, professor of urology, Johns Hopkins University School of Medicine, Baltimore, was presented with the Keyes gold medal of the American Association of Genito-Urinary Surgeons during

its recent annual meeting in Quebec. In bas relief on one side of the medal is a portrait of Dr. Edward L. Keyes, who died in 1924, and the other side carries the inscription "for contributions to the advancement of urology." Dr. Young graduated from the University of Virginia Medical Department in 1894 and has been associated with Johns Hopkins since 1895. He was president of the American Association of Genito-Urinary Surgeons and the American Urological Association in 1909 of the Medical and Chirurgical Faculty of Maryland in 1911, 1912, and of the International Congress of Urology in 1917. Dr. Young has written several volumes on urology and is the founder and editor of the *Journal of Urology*.

Bequests and Donations—The following bequests and donations have recently been announced:

- White Plains Hospital, White Plains, N. Y., \$75,000 from an anonymous donor as a memorial to the late Dr. Henry Ernest Schmid.
- The following hospitals in New York received bequests from the late R. Bleecker Rathbone: White Plains, St. Luke's Hospital, \$65,000; St. Mary's Hospital for Children, New York, Orthopedic Dispensary and Hospital, New York, Nursery and Child's Hospital, Hospital for Ruptured and Crippled, Home for Incurables and Babies, Hospital House of Rest at Sprain Ridge, Yonkers, \$15,000 each.
- A trust fund of \$200,000 was established in the will of the late Howard B. Magruder to establish and maintain a hospital at Port Clinton, Ohio. Dr. Carl J. Yeisley, Port Clinton, is chairman of a board of trustees appointed to administer the fund.
- Montgomery Hospital, Norristown, Pa., \$5,000 by the will of Miss Mary Fornace.
- Ahington Memorial Hospital, Ahington, Pa., \$20,000 from the annual June fête given by the woman's auxiliary.
- The will of Anne T. Fischer provided the following bequests: St. Francis Hospital and St. Joseph's Hospital for Consumptives, \$10,000 each; Misericordia Hospital, \$5,000; and St. Rose's Free Home for Incurable Cancer, \$2,000. All are in New York.
- New York Foundling, St. Vincent's and Mount Sinai hospitals, New York, \$1,000 each from the estate of Morgan O'Brien.

Estimate of Life Earnings—A study of life earnings in sixteen occupations placed medicine at the top of the list with \$108,000 for a working span of forty-two years, according to a report in the *New York Times*, July 14. Prof. Harold F. Clark, in charge of educational economics at Teachers College, Columbia University, New York, and a staff of research work-

Life Earnings in Sixteen Occupations

Occupation	Working Life Span	Present Value of Average Earnings for a Working Lifetime
Medicine	42	\$108,000
Law	43	105,000
Dentistry	45	95,400
Engineering	43	93,300
Architecture	43	82,500
College teaching	44	69,300
Social work	45	51,000
Journalism	46	41,500
Ministry	44	41,000
Library work	46	35,000
Public school teaching	45	29,700
Skilled trades	44	28,600
Nursing	40	23,300
Unskilled labor	44	15,200
Farming	51	12,500
Farm labor	51	10,400

ers spent eight years in the study with results shown in the accompanying table. In explanation of the purpose of the study, Dr. Clark said that occupational guidance is being given in disregard or ignorance of wages in the different occupations. He declared that income is the best measure of the relative need in all socially desirable occupations. "Although the professions may seem to be very badly crowded, in the light of the incomes of unskilled labor, farming and even of skilled labor there is no doubt that by and large the professions need many people in them," he observed. "Professional service is a type of service that people are willing to pay more for because it is scarce."

FOREIGN

World Conference on Leprosy—The fourth International Conference on Leprosy will be held in Cairo, Egypt, beginning March 21, 1938, under the auspices of the International Leprosy Association, formed in 1931. The three previous conferences were held at Berlin in 1897, Bergen in 1909 and Strassbourg in 1923. The Egyptian government is inviting all countries concerned to send official delegates and in addition, physicians and others interested in the subject are invited to be present. Full information may be obtained from the secretary of the International Leprosy Association, 131 Baker Street, London W. 1.

Sesquicentennial of Purkinje—A jubilee celebration of the one hundred and fiftieth anniversary of the birth of Jan Purkinje, the physiologist, is being arranged in Prague for September under the patronage of Eduard Benes, president of the Republic of Czechoslovakia. Purkinje was born Dec 17 1787, in Libochovice in northwestern Bohemia and studied medicine at Charles University in Prague. After his graduation he was first appointed assistant in anatomy at his alma mater and later became professor of pathology at Breslau, Germany, at the age of 33. At Breslau in 1842 he established what is said to have been the first separate department of physiology in Europe. In 1850 he established a department of physiology at his alma mater in Prague, where he died July 28, 1869.

International Tuberculosis Meeting—The tenth conference of the International Union Against Tuberculosis, postponed from 1936, will be held in Lisbon, Portugal, September 5-9, under the chairmanship of Prof Lopo de Carvalho. Topics of discussion will be: Radiological aspects of the pulmonary hilus and their interpretations; primary tuberculous infection in the adolescent and the adult, the open case of tuberculosis in relation to family and domestic associates. The speakers from the United States will include Drs Charles J Hatfield, Philadelphia, secretary of the National Tuberculosis Association, Henry C Sweany, Chicago, and Robert E Plunkett of the New York State Department of Health, Albany. Information concerning the program and other details may be obtained from the National Tuberculosis Association, 50 West Fiftieth Street, New York.

Deaths in Other Countries

Dr Felix de Lapersonne, French ophthalmologist at one time president of the International Association for the Prevention of Blindness, in 1934 received the Leslie Dana Medal awarded by the National Society for the Prevention of Blindness of the United States in cooperation with the St Louis Society for the Blind, died July 5, aged 84.

Government Services

Dr McCoy Studies Leprosy

Dr George W McCoy, former director of the National Institute of Health, Washington, D C, has been assigned by the U S Public Health Service to make a study of leprosy in continental United States and the island possessions, according to the *New York Times*. It was stated that the American Mission to Lepers, of which Dr McCoy has been for many years an honorary vice president, will place at his disposal its facilities for contact with the 200 leper colonies and clinics of Protestant churches throughout the world.

Maryland Free from Bovine Tuberculosis

Maryland became a modified accredited area July 1 the forty-fourth state to eradicate bovine tuberculosis. Three other states were successful in tuberculin-testing work during June. California reported the following counties for modified accreditation: El Dorado, Lake Sacramento and Yuba. New York reported the necessary progress in Chenango, Delaware, Lewis and Otsego, while South Dakota reported Brown, Hyde, Jerauld, Moody and Spink. Seven municipalities were accredited in Puerto Rico.

Examinations for Army Medical Corps

The War Department announces that an examination will be held September 13-17 for the purpose of qualifying candidates for appointment as first lieutenants in the Medical Corps, U S Army, to fill vacancies occurring during the fiscal year 1938. The examination is open to all male graduates of recognized medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years old at the time it is possible to tender a commission. The examination will be conducted by boards in various parts of the United States and will consist of a written examination in professional subjects, a physical examination, and a determination of the candidate's adaptability for military service. Full information and application blanks may be obtained from the Adjutant General, War Department, Washington, D C. Applications must be received before August 31.

The Treatment of Pleural Effusion

In a discussion at the Royal Society of Medicine, Dr Burton Wood said that the commonest cause today of pleural effusion in the tuberculous was trauma. Better than treating a pleural effusion was not to provoke one to remember that a blunt needle will lacerate the pleura, that a drop of alcohol left on a needle may cause intense irritation, that cold air injected into a warm pleural cavity may provoke reaction, or a positive pressure lead to effusion by the stretching of or tearing of adhesions. The man who cannot use his needle as an artist should turn to less delicate work. Any pleural puncture may be the first step toward thoracoplasty.

Many pleural effusions do not require active treatment. They are benign and may be protective in effect if not in intention. Thus a pleural effusion is the commonest manifestation of intrathoracic tuberculosis in childhood and appears to be analogous to other reactions of allergic type seen in child contacts. Such effusions have little effect on health, sometimes disappear very rapidly, and are rarely followed by parenchymatous disease. Some of the adolescent pleurisies are of similar type. Hence a young person with a "simple" pleural effusion, who is possibly in a hypersensitive state, should not be exposed to the risk of further infection, e g, by sharing a sanatorium cubicle with a patient with "open" pulmonary tuberculosis.

Dr Wood asked: What is the after-history of patients whose lungs are apparently otherwise sound at the time of the effusion? We have been taught that the expectation of subsequent phthisis is from 40 to 50 per cent, but recent Scandinavian figures suggest that 90 per cent make a lasting recovery. In a series of thirty cases occurring in young persons (from 15 to 35 years of age) Dr Wood found during an average observation period of five years that twenty-seven remained well and that the remaining three who died were all examples of bilateral pleurisy.

Before the advent of radiology the condition of the lung underlying the effusion was often in doubt. If effusion is suspected, x-ray examination should precede exploration. Blind tapping is justifiable only for the relief of urgent symptoms. If the disease runs a favorable course, the fluid will be spontaneously absorbed, but if it is of less benign type, aspiration will only lead to fresh outpouring of fluid, which will thicken as aspirations are repeated. The end result will be empyema. It is true that fluid, if left, will ultimately cause pleural thickening, but this is a conservative process. Fibrosis begins where tuberculosis ends.

The presence of a tuberculous focus in the underlying lung is sometimes assumed, and this has given rise to the practice of air replacement. This treatment is based on speculation, unless the effusion is known to cover diseased lung. But when the large size of an effusion causes mediastinal displacement or distress, air or oxygen replacement is necessary, but it is useless to try to prevent reaccumulation by pneumothorax. If hectic fever persists, an aspiration will sometimes be followed by a fall of temperature. It is justifiable to try this, with or without replacement, but repeated aspirations are undesirable.

Many of the effusions complicating pneumothorax are benign in their effect. An incomplete collapse is sometimes thus converted into a complete one and a cavity held out by adhesions closed. If an effusion rapidly fills the pleural space, it is tempting to replace it by air in the hope of maintaining a controlled collapse, but the result is usually reaccumulation, and recurrent aspirations bring the risk of empyema.

As intrapleural pneumolysis increases the risk of pleural effusion, Dr Wood questions the increasing practice of dividing adhesions in the early weeks of a pneumothorax before its efficacy can be fairly judged. When a serous effusion is followed by tuberculous empyema, anxiety is inevitable, though it may remain latent for years and not appear to affect the patient's health. Repeated aspirations then involve the grave risk of secondary infection. Conservative treatment is the best in most cases, especially in the young.

In cases of infected tuberculous effusion the need for action is urgent, but in the less virulent cases gelatinothorax should be tried before instituting closed drainage by intercostal catheter and negative suction.

Recognition of Opticians for Sight Testing

Surprise and dissatisfaction have been widely expressed in the medical profession by the proposal of the Ministry of Health to recognize opticians for sight testing in the regulations for the provision of spectacles under the national health insurance act. The *British Medical Journal* terms the proposal "profoundly disturbing" and points out that it is considerable advance in the direction of statutory registration of sight-testing opticians, which has not only been vigorously opposed by the British Medical Association during the past thirty years but has been reported on unfavorably by governmental departmental committees. In a letter to the *Times*, Dr G. C. Anderson, medical secretary of the association, says that the regulation is contrary to the whole weight of expert opinion. An analysis of 30,000 consecutive cases of ocular disturbances showed that in 27.6 per cent these were due to causes other than errors of refraction, while in 7 per cent there were similar disturbances without any error of refraction. Opticians, ignorant of diseases of the eye, will in most cases prescribe glasses for all sorts of trouble. In a letter to the *Times*, Sir John Parsons, past president of the Royal Ophthalmological Society, states that it is by no means infrequent for the ophthalmic surgeon to see cases of grave loss of vision which has resulted from sight-testing opticians failing to recognize disease conditions. He has had patients suffering from chronic glaucoma thus overlooked and in one case from malignant intra-ocular tumor. Mr Malcolm Hepburn, honorary secretary of the Council of British Ophthalmologists, points out that there are a great many varieties of the normal which, to the improperly educated observer, may simulate disease conditions of the eye, and it often requires all the medical training of the ophthalmic surgeon to decide whether they are of importance or not. When the sight-testing optician observes them he advises the patient to seek medical opinion, thereby creating fear of danger to the sight, which it is sometimes very difficult for the ophthalmic surgeon to dispel. Had he been consulted in the first instance, this would have been avoided. Secondly, the optician seems to have little idea regarding the relation between errors of refraction and eye diseases, and this leads him to order glasses "to prevent loss of sight." Thus the patient is frightened into wearing glasses that may be entirely unnecessary.

Increase in Court Claims for Dermatitis

The Wholesale Textile Association is exercised by the frequency with which claims are made for dermatitis said to be produced by articles of clothing and has held a conference to discuss what steps should be taken to resist unjustified claims. Originally claims of this kind arose in respect to furs and dermatitis was generally supposed to be due to the wearing of furs which had been treated with inferior dyes. Recently, however, claims have arisen with regard to every type of clothing, including gloves, dresses and underwear. Apart from people who endeavor, the association alleges, to make a living out of dermatitis claims, there are a certain number of persons among the general public suffering from an idiosyncrasy to dermatitis. In this case the fault may be said to be with

the person and not with the garment. It is on these persons that the responsibility rests not to wear apparel that is irritant to them but harmless to the general public.

Claims for dermatitis frequently arise in connection with the use of hair dyes, particularly paraphenylenediamine. A case has just been heard in which heavy damages were awarded at Manchester. A woman sued "Oloxo Limited," London, and a local hairdresser for negligence. She alleged that after the application of a hair dye called "Oloxo" she suffered from dermatitis and her face became so swollen that she could not see for three days and went through an agonizing time. The hairdresser claimed an indemnity from "Oloxo" on the ground that she was assured that "Oloxo" was harmless. The judge said that "Oloxo" was not as warranted. It was not safe for application to the head—the purpose for which it was sold. The makers knew this, for the manager had said that he regarded it as dangerous to use without a skin test. Yet they gave a warranty that it was safe. The judge awarded £2,600 damages.

The Paris Exposition

In the special exposition number of the *Presse médicale* June 26, is a description of the exhibits illustrating the progress that has been made in medicine, surgery and microbiology. Prof. G. Roussy, dean of the local medical school, and Dr. Justin-Besançon, also of Paris, were in charge of assembling the exhibits for the section on internal medicine. There are five large booths in which the principal discoveries made in the different branches are presented in a manner that will make it easy for the public to understand, without sacrifice of the essential scientific aspects of the subjects. The various steps in medical discoveries from the beginning of the nineteenth century to the work of Pasteur are well shown. The army medical and public health services have exhibits that do credit to their splendid organization in France. One booth is devoted to clinical thermometry and calorimetry, with demonstrations of how the basal metabolic rate is determined. The various physical methods (roentgenography, roentgen therapy, radium therapy, ultraviolet therapy and pyrotherapy) are well illustrated. In the Claude Bernard section, recent advances in diseases of nutrition and of the alimentary tract receive a good deal of attention. A chart illustrating the location and function of the endocrine glands makes this subject easy to understand.

In hematology, special stress is laid on the treatment of anemias and leukemias. In neurology, numerous sections and diagrams attempt to show the progress in this field. The wax models from the museum of the St. Louis Hospital, which are familiar to every syphilologist and dermatologist who has ever visited Paris, form an important part of the exhibit at the Grand Palais.

The surgical portion was organized by Prof. A. Gosset and Dr. Fredet. The dominant idea was to concentrate on three subjects: anesthesia, asepsis and transfusion. In the first named the exhibit was arranged by Dr. Robert Monod and in the last by Dr. M. Tzanck. The anesthesia exhibit consists of a series of units showing the various anesthetic agents employed at present. The various types of apparatus for general (inhalation) anesthesia, the method of using carbon dioxide as an adjuvant, intravenous administration of barbiturates for general anesthesia, and spinal, local and rectal technique are all shown in a way to make them easy for visiting physicians to understand. With the aid of Mr. Walter, an experienced hospital architect, the various methods of obtaining aseptic operating conditions are shown in a series of models of sterilizing and operating rooms. In the transfusion exhibit, the technique of blood grouping and of giving transfusions are well shown.

The section of microbiology is dedicated to the work of Pasteur and its results. The description of the exhibit is written

by Pasteur Vallery-Radot, Pasteur's grandson, an eminent clinician here. The various discoveries of Pasteur are arranged in chronological order. In addition, photographs of Pasteur and his co-workers, laboratory notes, letters and reproduction of autographs will be of great interest to visiting bacteriologists. The results of Pasteur's discoveries are shown under the headings of serums and serotherapy, use of toxoids (anatoxins) and associated vaccinations.

THE HYGIENE BUILDING

Medical visitors to the exposition will find that the building which has been constructed under the supervision of Professor Tanon contains many exhibits of great interest. Diagrams and models illustrate every problem relating to hygiene of large agglomerations, such as garbage disposal control of infections, disinfection, antepartum clinics, vaccination services, and diagnostic laboratories for syphilis, tuberculosis and cancer. There are many films devoted to social hygiene problems. One exhibit shows how an insanitary dwelling can be changed so as to make it habitable. The methods of obtaining a good water supply and the disposal of sewage are well illustrated in another stand. Food inspection is given a prominent place. The development of the individual from birth and the efforts which preventive medicine is making to reduce mortality are shown in an excellent manner. Social medicine is represented by exhibits of the work of antituberculosis and syphilis dispensaries, and that of anticancer centers.

MEDICAL MEETINGS DURING THE EXPOSITION

American physicians who intend to visit the Paris Exposition this summer and fall may find the following schedule of meetings of interest:

July 1	10	Daily programs for those interested in public health
	3	5 National Hospital Congress
	4	Meteorological and Biometeorological meeting
	4	11 National Dental Congress
	5	11 International Hospital Congress
	6	Special meeting of Academy of Medicine devoted to colonial medicine
	7	Aeronautic medicine
	8	11 General Council of International Association of Physicians
	8	10 International neurologic reunion
	11	17 International Congress of Medicine Applied to Sports and Physician Education
	12	13 International Congress of Public Health Works
	12	17 International Sanatorium and Private Hospital Congress
	16	18 International Psychotherapy and Comparative Psychology Congress
	19	21 International Congress for Protection of Children
	19	25 International Mental Hygiene Congress
24 Aug	1	International Infantile Psychiatry Congress
	25	31 International Psychology Congress
September	5	9 Conference of International Union Against Tuberculosis
	13	15 Congress of International Gastro Enterologic Society
	29	Oct 2 International Congress of Blood Transfusion
	30	Oct 2 French Gynecologic and Obstetric Congress
October	4	9 French Surgical Congress
	4	9 French Urologic Congress
	7	9 Orthopedics daily conferences
	7	9 International Scientific Press Association Congress
	7	14 Medical Photographic and Cinematographic Congress
	9	Conference (International) on Rheumatology
	14	17 Tourism Thermalism and Climatism (International) Congress
	17	French Society for Esophagoscopy and Bronchoscopy
	18	20 French Otorhinolaryngologic Congress
	18	20 French Hygiene Congress
	20	21 International Public Health Officers Congress
	25	28 International Food Congress

During the exposition, special graduate courses will be given in the various public hospitals of Paris. Information may be obtained by writing to Mlle Hure, Salle Beclard, 12 rue de l'Ecole de medecine, Paris.

International Congress on Rheumatism

The French Antirheumatism League will hold a meeting October 9 next in Paris in which a number of papers will be read on the use of radioactive preparations in rheumatism. A clinic will be given by Professor Loeper in the morning at the Hopital Saint-Antoine, and the afternoon session will be devoted

to papers on radioactive medication, emanotherapy, the radio-activity of waters at certain health resorts, and allied subjects. These papers will appear in the October issue of the *Revue du rhumatisme*.

French Otorhinolaryngologic Congress

The forty-second annual session of the French Otorhinolaryngologic Congress will be held in Paris, October 18-20. The subjects chosen for special reports are indications and results of intracranial operations on the auditory nerve, by Aubry and Ombredanne of Paris, and acute inflammation of the larynx and hypopharynx in children by Le Mee, Bloch and Bouchet. Information can be obtained through M. Raumont, Office medical, 17 rue de Bucy, Paris.

New Developments in Genetics

The German Society of Genetics held its convention recently at Frankfurt-on-the-Main. Johannes Lange, Breslau psychiatrist, spoke on "The Limits of Environmental Influence on Inherited Characters in Man." The special difficulties of this problem can be solved only by research on twins, he believes. In a study of two pairs (one male pair and one female pair) of enzygotic twins, it was observed that one member of each pair showed a physical defect: harelip in one and oxycephaly in the other. There were other marked dissimilarities between the normal and the afflicted twin in each instance. Serologic variations were also frequently observed in twins of discordant development. Differences in thyroid activity were observed in new-born enzygotic twins, the weaker twin often had the larger thyroid. Frequently the "concordance" of enzygotic twins is far from complete. The tendency may be termed concordant, but differences can exist in the degree to which it manifests itself. It would seem that phylogenetically "restless" traits are apt to be unstable, the vertebral column is an example. The occasionally abnormally low weight of twins at birth shortens their expectation of life. Infants who are weak at birth are further endangered by nutritional disturbances, and the sexual development of twins of unequal weight can also assume divergent form. If the twins are underweight, there will be a corresponding retardation of mental development. Whatever developmental process has been completed in utero can be changed later only by violent means and here too the variability of pathologic predispositions appears greater than that of normal predispositions. In any case the evaluation of the post-partum environmental influences is most uncertain. Thus twins affected with diabetes mellitus cannot be changed in this respect. In allergies the circumstances of concordant manifestation vary, thus, certain allergies seem to bar the way to others. Emotional experiences or protracted unemployment may lead to manifestations of serious illness in one of a pair of twins, while the other remains healthy. Discordances to manic depressive insanity have been recorded, the twin possessing the more melancholy temperament is more likely to become insane. The etiology of the frequently wide difference in temperament itself appears to lie in an antenatal sensitivity of the temperamental bases. Lange also believes that schizophrenia may arise from a developmentally unstable predisposition and that epilepsy may originate in developmental defects with a hereditary basis.

In the discussion that followed the reading of Lange's report, Prof. Otmar von Verschuer emphasized that today in contrast to former times the stress is increasingly on the discordances, one should remember, however, that in research on twins a maximal opportunity to observe environmental influence is assured. Prof. Eugen Fischer, anatomist, believed that the discordance in enzygotic twins is no greater than the difference between the right and left sides of an individual human body.

There is, for example, no right and left vertebral column. Since the hereditary predispositions are identical for right and for left, the variations must be conditioned by development alone. Therefore the differences between enzygotic twins cannot be regarded as of decisive importance.

A report by W. Lehmann of Breslau dealt with the hereditary pathology of hyperthyreoses. Besides definite exophthalmic goiter there may be a number of transitional states in which the sum of hereditary predispositions assumes a pathogenic role. Environment must also be granted importance. Of ten pairs of twins studied, two pairs of enzygotic twins were found to be concordant and one pair discordant, whereas, of seven pairs of dizygotic twins, six were discordant. Extensive investigations of families disclosed a wide distribution of both severe and mild symptoms of thyroid disease. This was cited as demonstrating that quantitative differences exist between the various forms of exophthalmic goiter. Women are more subject to this disorder than men.

Extensive investigations of "The Question of Heredity in Rheumatic Disorders," by Ferdinand Claussen of Frankfurt-on-the-Main led him to conclude that chronic rheumatism is inextricably bound up with heredity. He found that, of twenty-five pairs of enzygotic twins, eighteen showed pathologic concordance, whereas of thirteen dizygotic pairs only five showed such concordance. It was noteworthy that talipes valgus and other forms of clubfoot were almost always constant in rheumatic persons. More than 50 per cent of rheumatic persons belong to the asthenic-hypoplastic group.

The Relation of Vitamin C to Infection

"Vitamin C and Defense against Infection" is the title of a paper in the *Klinische Wochenschrift* by Dr. S. Thaddeus, assistant at the university clinic. Although the action of cevitamic acid has been investigated, little has been known of its role in the infections. Clinical medicine, however, has shown a growing interest in the destiny of cevitamic acid in the intoxications and infections. Experimental and clinical tests have demonstrated the decisive role of the adrenal glands in the defense of the organism against infection. Changes in the adrenals are present in acute infections together with clinical symptoms indicative of cortical dysfunction. Normally the adrenal cortex is of all parts of the body the richest in vitamin C. Favorable results can be obtained in diphtheria toxin intoxication and in infectious diseases by enriching the cevitamic acid content of the adrenal cortex. In experimentation with diphtheria intoxication of guinea-pigs, the percentage of survivals among animals which had received the vitamin treatment was greater than among the control animals. The adrenals and liver of treated animals were observed to be completely normal, whereas these organs in the control animals showed marked changes due to the inflammation and, in addition, an obvious deficiency in vitamin C content. In experimental tuberculosis of guinea-pigs, the loss in weight of the experimental animals is arrested and the life span lengthened. In pneumococcal sepsis of the white mouse, too, the typical picture is less pronounced and the liver suffers less damage if the animal has received preliminary treatment. Thus there is experimental evidence indicating that the administration of vitamin C leads to a remarkably strengthened resistance to various intoxications and infections, while further organic changes take place only in slight degree or are entirely lacking.

From a clinical standpoint these experiments demonstrate that the elimination of vitamin C in the urine at the height of acute infection or in the more severe febrile types of pulmonary tuberculosis may be especially low. Obviously there exist certain connections between the height of the fever and the excretion of cevitamic acid. Experimentation with intravenous injection of cevitamic acid has demonstrated that acute infectious diseases and exudative types of pulmonary tuberculosis are accompanied by an increased demand for vitamin C. In con-

trast to healthy subjects, persons suffering from infectious disease retain a greater part of the administered cevitamic acid in order to replenish the depleted vitamin C reserve. Conversely, persons affected with sclerotic forms of tuberculosis fail to present any demonstrable deficit in vitamin C. In tuberculous pulmonary hemorrhages too the vitamin C excretion is manifestly lowered, but after the bleeding has stopped the values rise again to normal. In acute infections and in the exudative and cavernous type of tuberculosis, the cerebrospinal fluid undergoes great depreciation of the vitamin C values. Administration of cevitamic acid raises the C level in the spinal fluid. The success of many tuberculosis diets, that of Gerson, Sauerbruch-Herrmannsdorfer, for example, may depend not alone on the exclusion of sodium chloride but in great measure on a rich supply of vitamins, especially vitamin C.

Developments in the Antivenereal Disease Campaign

By the terms of the law of June 1, 1933, the granting of small loans to couples who wed is contingent on the results of an official medical examination. No loan is granted to any applicant who is suffering from a venereal disease which carries with it the danger of contagion. Practically, this mandatory examination was the basis for a refusal of subsidies to 9,065 (27 per cent) of 333,776 applicants during the latter half of 1934 and the first half of 1935. The rejection of 547 applications was based on the existence of a contagious venereal disease: syphilis in 422 instances and gonorrhea in 125 instances. In addition, 209 rejections were made on the grounds of sterility and incapacity for child-bearing, conditions which also may be traced in great measure to some venereal infection.

The law of Oct. 18, 1935, stipulates that a marriage cannot be contracted if one of the betrothed is affected with a contagious disease that might endanger the health of the marriage partner or of the offspring. An engaged couple must obtain from the bureau of health a certification to the effect that no such impediment to marriage is present. The German Anti-venereal Disease Society under the presidency of Professor Spiethoff has formulated the following guiding principles with respect to potential contagion. Syphilis is generally considered contagious for four years subsequent to infection. Syphilis is considered as no longer transmissible if four years has elapsed since infection and if after an adequate therapy no symptoms have been manifested for two years. The foregoing periods may be shortened on the basis of scientifically established cure. In gonorrhea in the male patient the urine and prostatic secretion must be negative for gonococci (even for threads) during at least one examination weekly over a period of three months. It is mandatory that these follow-ups be based on recognized scientific provocative tests. If the data so warrant, a shorter period of observation will be deemed sufficient. In the case of a woman gonorrhea patient, it is stipulated that after completion of treatment three months should elapse during which no gonococci are demonstrable (in the urethra, cervix, gland of Bartholin or rectum) at follow-ups conducted at least once each week. As in the case of the man, proper provocative tests are compulsory. Examination before, during and immediately after menstruation is particularly conclusive. Here too the period of observation may be shortened on the basis of satisfactory scientific proof of cure. The record, only just made public, of violations of the antivenereal disease law during 1933 is as follows. In all, 346 defendants were convicted, almost exactly the same number as in 1932. Of these 346 persons, 196 were sentenced for indulging in coitus while afflicted with a venereal disease, two for contracting marriage while afflicted with a venereal disease and failure to inform the partner of the illness, 13 for unauthorized treatment of venereal disease and offers to perform such treatment, twelve for attempting to sell appliances alleged to cure or palliate venereal disease and there was one conviction for violation of the clause which prohibits the suckling of infants by venereal disease sufferers.

JAPAN

(From Our Regular Correspondent)

May 31, 1937

The National Health

In the present session of the imperial diet, Mr Hasama, chief of the board of health, discussed the health of the nation. The present inclination of the birth rate is slightly downward but it is high in comparison to that of other countries, being 30 per thousand of population. The higher rates are found in the northern provinces and the lower rates in the larger cities and the middle parts of the country. The death rate was 18.1 per thousand in 1934. More than 130,000 persons died of tuberculosis in 1934, the rate being 19.3 per 10,000 of population including more than 96,000 persons who died of pulmonary tuberculosis. There were about 49,000 cases of dysentery in 1935, 7 per 10,000 of population, and more than 15,000 deaths. According to the investigation made by the home office of 152,050 villagers who were examined by the official experts 118,000, about 78 per cent, had infestation with some kind of parasite. There are reported to be more than 7,000,000 cases of trachoma throughout the country. The number of insane increased and was greater than 83,000 in 1935. Venereal diseases also increased. The physical examinations of conscripts revealed that the number of those who fail the medical tests are regularly increasing every year throughout the country. The cause, however, is not clear. The home office has planned to establish this year as many health centers as possible in all parts of the country.

Decrease in Beriberi

It has been almost positively proved that the chief cause of human beriberi is a deficiency of vitamin B₁. Among the poorer classes, however, whose economic condition prevents them from taking sufficient nourishment, there are still many cases of this disease. Dr Yanagi of the Izumibashi Charity Hospital reports that he found 126 cases of beriberi (14.2 per cent) among 888 patients who came to his department recently to consult him. The percentage of cases of beriberi has shown no change in his hospital in the past ten years. Ten per cent of the patients were suffering from this disease every year. The number of male and female patients has remained almost the same. The greater number are between 15 and 20 years old. Among the women, many are from 25 to 30 years of age, the condition probably being due to pregnancy. Beriberi is on the decrease except among the poorer, and if they could have sufficient vitamin B₁, it could easily be prevented among them.

Physical Examinations at Schools

The general tendency, seen in the physical examination for conscription, that young men are becoming constitutionally weaker every year, has attracted much attention. At the Tokyo Imperial University it has been announced that the physical examination of the students henceforth will be done differently from that of former days. What it needs is not the recording of physical development but guidance of students to better health. Students were formerly examined with the stethoscope only but now they will also, if necessary, be roentgenographed.

The Association of Hematology

The *Journal of Pathologic Haematology* which has been issued for the last six years under the supervision of Prof Dr Katsunuma of the Nagoya Medical College has been instrumental in organizing the Japanese Society of Hematology. The society decided to hold its annual meeting as a branch of the Japan Medical Conference, which is to hold its general meeting in the spring. The title of the Journal will hereafter be *Japanese Haematology* and it will be published bimonthly and will contain original reports of researches on the blood. Drs Kiyono of Kyoto, Mitamura and Sato, of Tokyo, Sugiyama of Kanazawa and Katsunuma of Nagoya are on the board of directors.

Deaths

Dr S Endo died April 20 at his home in Tokyo, at the age of 68. He was very modest and known by few even in this country, but "Endo's Medium" is almost universally recognized. While working in the Kitazato Research Institute in Tokyo, he succeeded in 1903 in inventing this culture medium, using Japanese isinglass. By means of Endo's medium it is easy to distinguish the typhoid bacillus from the colon bacillus.

Dr J Shimazono, honorary professor at Tokyo Imperial University, died April 27 of pneumonia, aged 60. He was born in 1877 in the city of Wakayama and in 1904 graduated from the medical college of the Tokyo Imperial University. He went to Germany in 1909 to study for three years. On returning, he was appointed professor at the Okayama Medical College, was given the degree of "Igakuhakushi" the next year, and three years afterward went to Kyoto Imperial University. In 1924 when his name had come to be widely known, he was transferred to Tokyo Imperial University as successor to the late Dr Kinnosuke Miura. In 1929 he went to Germany as an exchange professor, lecturing one year at Berlin University. His investigations on the cause of beriberi are famous. He was the director of the hospital attached to the university, and also of the Izumibashi Charity Hospital.

NETHERLANDS

(From Our Regular Correspondent)

April 27, 1937

The Fight Against Bovine Tuberculosis

Since 1920 the fight against the spread of tuberculosis among cattle has gone forward relentlessly in Friesland, but it has been effective only where the individual farmer is a constant active participant. According to statistics compiled by the antituberculosis society, the number of reactive animals has greatly diminished since 1923. During 1935 declines were reported of from 15 to 3 per cent in certain regions, elsewhere the drop was from 28 to 7 per cent, from 37 to 6 per cent and from 39 to 11.8 per cent. Not a single case of tuberculosis has been reported for two years among the cattle on the island of Ameland. Two important procedures of the campaign are the isolation of cattle infected with open tuberculosis and the periodic examination of specimens of milk. The country folk have become convinced that open tuberculosis constitutes the greatest danger to stock raising. The separation of reactive from nonreactive cattle is of great difficulty and a favorable result can be attained only after a regular inspection has been instituted. Certain tuberculous animals are submitted to monthly, in some instances quarterly, examinations, the results have been gratifying from both a clinical and a bacteriologic point of view.

Regulation of Dilutions of Diphtheria Toxin

Special conditions to which the dilution of diphtheria toxin must comply have been stipulated by the minister of social service. Diphtheria toxin cannot be administered save in the form of dilution susceptible of being used for intracutaneous injections in the Schick test. The diphtheria toxin content of this dilution or "Schick fluid" cannot, per cubic centimeter of dilution, exceed 0.1 of the quantity of toxin that would prove lethal to a guinea-pig weighing 250 Gm within a period of four days, 0.2 cc of this dilution, namely, 0.02 of the minimum lethal dose is considered to be a "trial dose" for the Schick reaction.

The dilution of diphtheria toxin designed to induce the Schick reaction must in addition comply with the following conditions: 1. Ten cubic centimeters injected, immediately after heating to a temperature of 37°C, intracutaneously into a guinea pig should kill the animal within a period between three times twenty-four hours and five times twenty-four hours. 2. One twenty-fifth of the trial dose if it contains 0.2 cc of a dilution

to 0.04 of the Schick fluid, when inoculated into the skin of a guinea-pig ought not to provoke any characteristic reaction. 3 One tenth of the trial dose, if it is 2 cc of a dilution to 0.1 of Schick fluid, inoculated into the skin of a guinea-pig ought to provoke a positive Schick reaction. 4 The trial dose mixed with 0.001 of an international unit of diphtheria antitoxin, inoculated into the skin of a guinea-pig, should provoke no reaction.

For the control reaction, the Schick fluid ought to be heated for at least ten minutes at 70 C in order to destroy specific toxin.

Ampules, bottles and other receptacles in which dilutions of diphtheria toxin for use in the Schick test are stored, transported or imported, together with their wrappers, must bear the plainly visible legend "Fluid for the Schick test, 0.2 cc for intracutaneous injections." In addition there must be set forth the date on which the fluid was supplied and the duration of its effectiveness. The latter must not exceed seven days from the date of supply. Moreover, explicit directions for use must appear either on the outside of each package or on an accompanying loose sheet. Further analogous regulatory measures have been promulgated which concern the preparations for active immunization against diphtheria.

Endemic and Sporadic Gorter

At a recent meeting of the Rumanian Scientific Academy, Dr. Danelopolu read a paper on his observations based on 40,000 cases of endemic and sporadic gorter. Accompanied by eight physicians and three veterinary surgeons, he visited some endemic districts of Rumania, namely, Sibiu, Storojinet (Bukovina), Tarnava Mare, the valley of Moldovita (Bukovina) and Alba. His observations led to the conclusion that economic circumstances predispose to the occurrence of endemic gorter. The condition cannot develop unless the diet is qualitatively and quantitatively insufficient. Endemic gorter develops in many cases under the influence of puberty and pregnancy. Women are more predisposed than men, for physiologic reasons. Danelopolu and his assistants usually found that the right lobe is attacked. They found different types of gorter: unilobar, either on the right or on the left side, bilobar, and special forms: cystic, vascular and lobular. Danelopolu also studied the hereditary background during his tour. According to his experience inheritance is not an important factor in the production of gorter.

Scarlet Fever in Children

The chief medical officer of health of the city of Cluj, the capital of Transylvania, publishes a statistical report on 645 children with scarlet fever. Of these 160 received complete inoculations and twenty-nine only single inoculations, while 456 received none at all. The mortality rate of the noninoculated children was twice as high as that of the inoculated ones: 8.9 and 3.7 per cent respectively. Complications were rather frequent among the noninoculated but strikingly infrequent among the inoculated. Milder forms of scarlet fever are encountered much more often in inoculated children than in those who are not inoculated; conversely, severer cases are more frequent among the noninoculated. The fact that rather severe cases of scarlet fever very infrequently occur in inoculated children less than 6 years old, while the disease is fairly frequent in the noninoculated ones, and beyond 6 years rather frequent even in the inoculated ones, allows the conclusion that antiscarlatina inoculations are more efficacious in early childhood. If it is admitted that inoculations do not influence greatly the morbidity of scarlatina, it is at any rate true that the mortality rate is less among the inoculated and the course of the

disease is milder. Drs. Vlad and Gaynal, city medical officers, of health in Cluj, suggest that systematic inoculations be made in children from 1 to 3 years of age, when these are most efficacious.

Tetanus Following Abortion

Drs. Mironescu and Bals report the following two cases. 1 A married woman, aged 31, developed tetanus fourteen days subsequent to septic abortion. She was admitted to the hospital on the seventh day after the onset of the first symptom with generalized tetanus, from twenty to twenty-five crises occurring hourly. She received antitetanic serum, antiscarlatinal serum and antigangrenous serum. After the tetanus serum had been administered daily for eight days, the symptoms of tetanus disappeared. 2 In a married woman, aged 29, the first signs of tetanus appeared fifteen days after abortion. She was admitted to the hospital on the tenth day with generalized symptoms. She received 3,400,000 units of antitoxin, whereupon the symptoms disappeared on the tenth day. Both patients made uncomplicated recoveries.

Epinephrine in Treatment of Chronic Malaria

There are still many cases of malaria in the proximity of the swamps, especially in the Dobruja district. Some prominent health officials suggested the introduction of the Ascoli therapy, which in Italy proved to be efficacious. The essentials of this treatment consist in daily injections of epinephrine beginning with 0.01 mg. and rising to from 0.05 to 0.1 mg. Either 0.05 or 0.1 mg. is usually repeated twenty times. This way of administration ensures that the organism tolerates this quantity of epinephrine well, so that in the majority of cases the treatment runs smoothly without the least disturbance. In instances of malarial splenomegaly with a spleen index of 4, a small increase in the dose of epinephrine is necessary of course only if it is well borne. Treatment with epinephrine is an important auxiliary in the treatment of chronic malaria, malarial splenomegaly, malarial anemia and cachexia.

Quinine as a Prophylactic Against Influenza

According to Dr. Winkel of Budapest, quinine was administered as a preventive of influenza fifty years ago, and, while it came into disrepute, attention has again been directed toward it. One of the Berlin children's homes that suffered often from influenza epidemics made a trial of quinine prophylaxis in January 1933 with a daily dose of 0.05 Gm. of quinine sulfate. Among 126 children, nine refused to take the drug, and six of these nine contracted influenza, while of the other 118 eight contracted influenza the first week, and no more cases supervened. At that time influenza raged in Berlin. The six children who refused to take quinine had severe influenza, while the others had only mild attacks.

More convincing are the results at the Graz clinic, where the prophylactic use of quinine has been tested on 173 nurses. Prior to the introduction of prophylaxis, 22 per cent of the nurses contracted influenza. After the administration of quinine (quinine hydrochloride and sodium salicylate, 0.25 Gm. of each), only 5 per cent fell ill.

Congress of the Latin Nations on Otorhinolaryngology

The Otorhinolaryngologic Congress of the Latin nations will be held in Bucharest September 16-19, under the presidency of Dr. Nicolai Metjanu, professor of otolaryngology at the University of Bucharest. The chief theme to be discussed will be Indications for Operation in Cases of Acute or Chronic Otomastoiditis. The general meeting of the Society of Bronchoesophagoscopy of the Latin nations will be held at the same time. Also the Rumanian Society of Otorhinolaryngology will hold its annual meeting. The organization of the congress has been entrusted to a committee of fourteen members, directed by Dr. Metjanu. Information may be had from Dr. I. Teodorescu, Bucharest, Strada Diomisie No. 50, Rumania.

Dr Ulmeanu Awarded Prize

The Parisian Academy of Medicine conferred a great distinction on a Rumanian physician, Florian Ulmeanu. The Boullard prize of 1,800 francs was accorded him for his treatise on Voluntary Movements and Chronaxia. Dr Ulmeanu is a distinguished scholar of the medical faculty of the Bucharest university and presently will become assistant of the Superior Institute of Physical Education. His prize-winning work was done under the direction of Professors Lapicque and Laugier, both of the Faculte des sciences in Paris.

ITALY

(From Our Regular Correspondent)

June 15, 1937

Meeting of Dermatologists

The Societa di Dermatologia e Sifilografia met recently at Pisa under the chairmanship of Prof Agostino Crosti. Prof Cosimo Lombardo reported results of staining leprosy and tubercle bacilli in living organisms, by means of direct injection of methylene blue in the skin. The method is of practical value and gives better results than are obtained by intravenous injections.

Professor Pinetti of Sienna reported results of the clinical and histologic study of a typical case of lupus pernio of Besnier-Tennesson type. The patient suffered from infiltration of the skin of the face and of the right arm as well as of the parenchyma and hilus of the lung. Roentgenograms of the hands showed pseudocystic rarefaction of some of the epiphyses of the phalanges. According to the speaker, the causation of the disease is unknown. His patient has no special taints nor does he suffer from tuberculosis or syphilis.

Prof Pietro Negri of Perugia reported a case of reticulohistiocytoma with sarcomatous degeneration. The biopsy done at different points of the tumor showed that the latter was diffuse, on the upper part of the back and associated with large spots of erythematous infiltration. During the last three months, metastases developed at the cervical and axillary lymph nodes and around the tumor. The histologic structure of the tumor is that of sarcoma with small round cells. Intensive roentgen treatment controlled the evolution of the tumor only temporarily. Transplantation of neoplastic tissues at the skin of the patient failed to take.

Professor Lisi discussed the filtrability of the syphilitic virus. He reviewed Levaditi's theories on the existence of an invisible granular phase of *Spirochaeta pallida*. The speaker made experiments on rabbits and attempted to detect latent infection by means of the serial passages through the inguinal lymph nodes and the systematic serologic examinations. Starting from scrotal syphiloma of rabbits, the filtration was done through a Chamberland filter No. 2, 3, 5 and 7 and a Berkefeld N filter. Even after four passages through the inguinal lymph nodes in a group of nine rabbits, a scrotal syphilomatous reaction did not take place. Only in two cases out of a group of eight rabbits did the serologic examination give slight positive results, which, on account of the proportion of nonspecific results (15 per cent) in normal rabbits, seem to be of no value. The speaker stated that the results of his experiments do not support the theory of the existence of a filtrable invisible virus of syphilis.

Romer Test

Professor Malesani of Padua, in a paper recently read before the Societa medica of that city, reported results of experiments on the influence of cholesterol and lecithin on Romer's test. The mixtures, intradermally given, were made up with 0.4, 0.5 or 1 cc of the toxin and the same amount of an ether solution which contained 4, 10, 16 or 20 mg of either fat. The dose for each injection was 0.1 cc of the mixture. The intramuscular injections were given in a mixture of a minimal lethal dose of diphtheria toxin, 0.3 Gm of cholesterol and 0.72 Gm of lecithin for each 250 Gm of the body weight

of the animal. The speaker concluded that the local toxic action of diphtheria toxin is neutralized by cholesterol in the proportion of 0.01 Gm of the fat for each thirtieth of the minimal lethal dose of diphtheria toxin or by lecithin in the proportion of one sixth of the fat for each forty-eighth part of the minimal lethal dose of the fat. Cholesterol and lecithin injected intramuscularly in the proportion of 0.3 Gm and 0.72 Gm respectively for each 250 Gm of body weight of the animal neutralize a minimal lethal dose of diphtheria toxin. Control animals that are given an injection of diphtheria toxin die with the signs and symptoms of diphtheria intoxication.

Statistics on Social Work

The Istituto di previdenza sociale, a center of social work, has reported on the work done. The center is concerned with providing insurance for invalidism, old age, tuberculosis, maternity and unemployment and also in financing social work of importance for the public. According to the latest statistics, 462,776 pensions for invalidism and old age are paid every year, the cost of which amounts to 401,495,000 lire (about \$20,074,750). The center maintains six hospitals for convalescents, ten bathing places and fifty-two dispensaries for treating patients with trachoma. The tuberculosis center has given attention to 287,000 persons from January 1929 to December 1936. There are now about 3,000,000 insured workers, including farmers. The center maintains forty-one institutions for the treatment of the disease. About twenty-two new centers for the care and treatment of insured tuberculous patients are in construction. The center for maternity insurance has seventeen clinics in function. Aside from medical care, the insured women are given certain amounts of money for other expenses in labor or abortion.

International Congress for Protecting Children

The second International Congress for Protecting Children will be at Rome, October 4-8. The first one was held at Paris in 1933. The welfare of children will be discussed in separate sections from social, forensic, hygienic and sanitary points of view. The topic for discussion at the hygienic and sanitary sections will be prevention of infant mortality due to nutritional diseases, establishment of climatic colonies for children of preschool age, care of the health of European children living in colonies, physical education of children attending grammar schools, and prevention of inferiority of health of illegitimate children. The general secretary to the congress is Prof G. B. Allaria of the pediatric clinic of Turin. Shortly before the congress takes place, the fourth International Congress of Pediatrics will be held in Rome.

Marriages

THORBORN S. MCGOWAN, Assistant Surg., U. S. Public Health Service, New London, Conn., to Miss Isabel Morrison West Jackson of Pittsfield, Mass., April 17.

SAMUEL E. WAY, Rocky Mount, N. C., to Miss Lilhan Pauline Dixon of Winston-Salem, in Nashville, April 14.

ROBERT MABRY DACUS JR., to Miss Bina La Verne Valentine, both of Greenville, S. C., in Pinckneyville, Ill., April 19.

WILLIAM P. HIXON, Birmingham, Ala., to Miss Roberta Mims Knowles in Atlanta, Ga., in April.

WILLIAM GARDNER MORGAN BENSON, N. C., to Miss Mary Virginia Neal of Bessemer, Ala., recently.

JACOB H. BROTMAN, Savanna, Ill., to Miss Sarah Paley of Clinton, Iowa, in Morrison, April 16.

WILLIAM BLOUNT NORWENT to Miss Katherine Williams, both of Greensboro, N. C., April 27.

BENAGER COLUMBUS TEASLEY JR., Atlanta, Ga., to Miss Mary Brooks of Robinson, Ill., April 13.

FRANK P. FIGUATARO Marlboro, N. J., to Miss Mary E. De Maria of Red Bank, April 22.

Deaths

Frank Kirkwood Hallock ♂ Cromwell, Conn College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, member of the American Neurological Association and the Association for Research in Nervous and Mental Disease, past president of the Connecticut State Medical Society, and the Boston Society for Psychiatry and Neurology, formerly bank president and president of the Cromwell Library Association member of the board of trustees of Wesleyan University, Middletown, an original incorporator and consultant in neurology to the Middlesex Hospital, Middletown, medical director of the Cromwell Hall, aged 76, died, April 29, of arteriosclerotic heart disease and cerebral thrombosis

John Blair Spencer, Gloucester, Va., University College of Medicine, Richmond, 1904, member of the Medical Society of Virginia and the American Academy of Pediatrics, at one time on the staffs of the Providence and Garfield hospitals, Washington, D C., surgeon in the U S Navy from 1916 to 1919, assistant director of public welfare for the city of Philadelphia, 1919-1920, director of all tuberculosis activities in the city of Philadelphia in 1921, associate director of public welfare for Philadelphia in 1922, director of public health for Philadelphia, 1923-1924, aged 54, died, April 30, of cardiovascular renal disease

Elmer Leslie Eggleston ♂ Battle Creek, Mich., American Medical Missionary College, Chicago, 1900, member of the American Gastro-Enterological Association, past president of the Calhoun County Medical Society, fellow of the American College of Physicians, formerly professor of chemistry and secretary at his alma mater, at one time instructor of pharmacology and therapeutics at the Detroit College of Medicine on the staff of the Battle Creek Sanitarium, member of the editorial council of the *American Journal of Digestive Diseases and Nutrition* aged 62, died, July 7, of coronary thrombosis

Edgar Bronson Smith ♂ Providence, R I., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1880 fellow of the American College of Surgeons, member of the New England Surgical Society consulting surgeon to the Rhode Island, Providence Lying-in and Butler hospitals, Providence Rhode Island State Sanatorium, Wallum Lake, Memorial Hospital, Pawtucket, and the South County Hospital, Wakefield, aged 83, died, April 9 in Orlando, Fla., of coronary thrombosis

Alphonso James McLaughlin, Sioux City, Iowa, Kentucky School of Medicine, Louisville, 1898, member of the Iowa State Medical Society, and the American Urological Association, served in the U S Public Health Service during the World War, fellow of the American College of Surgeons, member of the staff and head of the genito-urinary section of St Joseph's Mercy Hospital, aged 60, died, April 18, of cerebral arteriosclerosis

Everett Mingus, Marshfield, Ore., University of Pennsylvania Department of Medicine, Philadelphia, 1892, past president of the Coos-Curry Counties Medical Society, fellow of the American College of Surgeons, city health officer and coroner for many years, served during the World War, on the staff of the Keizer Brothers Hospital and Mercy Hospital, North Bend, aged 69, died, April 22, of coronary thrombosis

Carl William Shaffer ♂ Major, U S Army retired Alexandria, Va., University of Virginia Department of Medicine, Charlottesville, 1915, also a pharmacist, fellow of the American College of Surgeons, served during the World War entered the medical corps of the regular army in 1920 and retired in 1933 for disability in line of duty, aged 50, was found dead, April 13, of a self-inflicted bullet wound

Charles Wesley Rook ♂ Montrose, Calif., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883, secretary of the Adams County (Ill.) Medical Society, 1887-1893, vice president 1893-1894 and president, 1894-1895, formerly professor of obstetrics at the Quincy (Ill.) College of Medicine, aged 78, died, April 15, of hypostatic bronchopneumonia, arteriosclerosis and hypertension

Winfield Ayres, New York, Bellevue Hospital Medical College, New York, 1893, formerly adjunct professor of genito-urinary surgery at the New York Post-Graduate Medical School, and chief of the clinic for genito-urinary diseases and demonstrator of anatomy at his alma mater, aged 72, died, April 12, in the New Milford (Conn.) Hospital, of carcinoma of the colon

Isaac Surnamer ♂ Paterson N J New York University Medical College, New York, 1896, fellow of the American

College of Physicians, consulting neurologist to the Paterson General Hospital, Hackensack (N J) Hospital, Paterson City Hospital and the Valley View Sanatorium, aged 64, died, April 23, of cerebral hemorrhage and arteriosclerosis

Joseph Malcolm Short ♂ Portland, Ore Detroit College of Medicine, 1896, assistant clinical professor of medicine at the University of Oregon Medical School fellow of the American College of Surgeons, aged 65, on the staffs of the Multnomah County Hospital and the Good Samaritan Hospital, where he died, April 30, of cerebral embolus

Gershom Franklin White, Washington, D C., George Washington University School of Medicine, Washington, 1909, served during the World War, aged 63, senior pathologist of the bureau of entomology and plant quarantine, U S Department of Agriculture, stationed at Moorestown, N J, where he died suddenly, April 27, of heart disease

James A Sherbondy ♂ Youngstown, Ohio Western Reserve University Medical Department Cleveland 1902 fellow of the American College of Surgeons, served during the World War, consulting surgeon to the Youngstown Hospital, aged 59, died, April 24, of hypertensive cerebral hemorrhage

Walter Reynolds, Atlantic City, N J University of Pennsylvania Department of Medicine, Philadelphia 1894 at one time city health officer, past president of the Atlantic County Medical Society, formerly vice president of the city board of education, aged 71, died, April 18, of coronary occlusion

Paul H Rupp, Wauwatosa, Wis Milwaukee Medical College, 1905, member of the American Psychiatric Association, medical superintendent of the Milwaukee Asylum for Chronic Insane, aged 55, died, April 6, in the Milwaukee County General Hospital, of septicemia and perirectal abscess

James Arthur Wigley, Mulberry Ark University of Arkansas School of Medicine, Little Rock 1912 member of the Arkansas Medical Society, past president of the Crawford County Medical Society and the Tenth Council District Medical Society, aged 64, died April 4, of angina pectoris

Samuel Pierson ♂ Stamford, Conn College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881, fellow of the American College of Surgeons, chief of staff and surgeon to the Stamford Hospital, aged 79, died, April 22, of arteriosclerosis and auricular fibrillation

Walter Rupert Weiser, Daytona Beach Fla., University of Pennsylvania Department of Medicine, Philadelphia, 1897 served during the World War, formerly on the staff of the Mercy Hospital, Springfield, Mass., and the Springfield (Mass.) Hospital, aged 67, died, April 13, of heart disease

Claude V Young, Lebanon, Tenn., Vanderbilt University School of Medicine, Nashville, 1893, member of the Tennessee State Medical Association, past president of the Wilson County Medical Society, health officer of Lebanon, aged 69, died, April 28, in a hospital at Nashville, of uremia

Joseph Emmitt Galvin, Fort Dodge, Iowa, St Louis University School of Medicine, 1918, member of the Iowa State Medical Society, aged 46, formerly city physician, on the staff of St Joseph Mercy Hospital, where he died, April 18, of coronary occlusion and mesenteric thrombosis

William Downing Stickley ♂ Fairfield, Ala., Tulane University of Louisiana School of Medicine, New Orleans, 1923 aged 38, on the staff of the Employees Hospital of the Tennessee Coal, Iron and Railroad Company, where he died, April 12, of spinal meningitis

Howard Milton Smith, Kansas City Mo., Long Island College Hospital Brooklyn, 1905, physician in the children's hygiene division of the city health department formerly superintendent of the Kansas City General Hospital No 2, aged 37, died, April 13, of pneumonia

George Ernest Peterson ♂ Waukesha Wis Milwaukee Medical College, 1901 member of the Radiological Society of North America, formerly public health commissioner aged 67, on the staff of the Municipal Hospital where he died April 21, of coronary sclerosis

Frank Edmund Shipman, Chicago College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912, served during the World War aged 49 died, April 8, in the Veterans Administration Facility, North Chicago, of cellulitis

George Livesey Van Deursen, Lowell, Mass Harvard Medical College and Hospital of Philadelphia 1896 also a dentist, member of the Massachusetts Medical Society aged 70, formerly on the staff of the Lowell General Hospital where he died April 15

Benjamin Franklin Sturgis Jr, Salem, Mass., Medical School of Maine, Portland, 1898, on the staff of the Salem Hospital, member of the exemption board during the World War, aged 62, died, April 29, of cerebral arteriosclerosis and encephalomalacia

Frank W Emery, Wichita, Kan., University Medical College of Kansas City, Mo., 1895, member of the Kansas Medical Society, member of the medical board of examiners for recruits during the World War, aged 73, died, April 9, of myocarditis

William Lee McClain, Scottsburg, Ind., University of Nashville (Tenn.) Medical Department, 1898, county health officer and formerly secretary of the county board of health, aged 68, died, April 10, of chronic myocarditis and arteriosclerosis

Frank Adam Hohenschuh Ⓢ Clinton Iowa State University of Iowa College of Medicine, Iowa City, 1900, city health officer, aged 62, on the staff of St Joseph Mercy Hospital where he died, April 28, of coronary occlusion and fracture of the hip

Charles C Shotts Ⓢ Poteet, Texas Memphis (Tenn.) Hospital Medical College 1902 secretary and past president of the Atacosa County Medical Society owner of the Shotts Hospital and Clinic, aged 58, died, April 26, of angina pectoris

Henry Thomas Sparks, Olive Hill, Ky., University of Louisville Medical Department, 1909 member of the Kentucky State Medical Association, aged 52 died, April 4, in the Stovall Memorial Hospital, Grayson, of cerebral hemorrhage

Harry Walter Woodruff, Joliet, Ill., Harvard University Medical School Boston 1933 resident in ophthalmology at the St Louis (Mo.) City Hospital, aged 29, disappeared, Dec 29 1936, and was found dead, April 27, near St James, Mo

John Wesley Muir, East Las Vegas, N M., Drake University College of Medicine, Des Moines, 1903, member of the New Mexico Medical Society, served during the World War, aged 61, died, April 30, of cerebral hemorrhage

Lewis Ellwood Davis, Pittsburgh Jefferson Medical College of Philadelphia 1881, member of the Medical Society of the State of Pennsylvania, aged 82 died, April 26 of cerebral hemorrhage and cardiovascular degeneration

Richard Wickham Sharpe, New York Medical College of Virginia, Richmond, 1936 served during the World War aged 43, intern at the Bellevue Hospital where he died, April 7, of scarlet fever contracted from a patient

Ernest Irving Woodbury, Burlington, Iowa Chicago Homeopathic Medical College 1894 member of the Iowa State Medical Society served during the World War aged 66 died suddenly, April 9 of coronary thrombosis

Alexander Ridgway, South Haven Minn Minneapolis College of Physicians and Surgeons 1894 member of the Minnesota State Medical Association, aged 81 died, April 3 of mitral insufficiency and arteriosclerosis

James Gregg McAlvin Ⓢ Waterloo, Iowa, State University of Iowa College of Medicine, Iowa City, 1897, aged 67, died, April 14, in St Francis Hospital, of an infection of the arm complicated by diabetes mellitus

Ernest Colpitt Steeves, Essex, Mass., Dartmouth Medical School, Hanover, N H, 1905, member of the Massachusetts Medical Society, a member of the board of health and school committee, aged 69, died, April 10

John Lewis Elwood, Maupin Ore Ensworth Medical College, St Joseph, Mo 1892, member of the Oregon State Medical Society, aged 66, died, April 6 at The Dalles, of cardiovascular renal disease

Victor Sheldon-Smith, Menlo Park Calif Kansas Medical College, Medical Department of Washburn College Topeka 1911, aged 56, died, April 17 in the University of California Hospital, San Francisco

John David Leonard Ⓢ Wagoner Okla Chattanooga (Tenn.) Medical College, 1909 served during the World War formerly health officer of Muskogee County aged 53 died April 24 of hypertension

Joseph Newton McCoy, Spokane, Wash., College of Physicians and Surgeons, Keokuk, Iowa, 1882 member of the Washington State Medical Association, aged 78 died, April 19, of cerebral hemorrhage

George E Youmans, Adrian Ga., University of Georgia Medical Department, Augusta, 1900 for many years postmaster, aged 60, died, April 9, in the Veterans Administration Facility, Augusta

Alvin G Tillotson, Michigan City, Ind Bennett College of Eclectic Medicine and Surgery Chicago 1870, formerly county coroner, aged 90 died April 29 in the Clinic Hospital of pneumonia

Jacob J Weaver Jr, Umontown, Md., University of Maryland School of Medicine, Baltimore, 1870, bank president, aged 88 died, April 10, in the Homeopathic Hospital, Washington, D C

Viola Elizada Shaw Terwilliger, Bradford Ill., Northwestern University Woman's Medical School, Chicago, 1898, aged 65, died April 21, in the Methodist Hospital, Peoria, of pneumonia

Richard Jessup Scofield, New York University of the City of New York Medical Department, 1890, member of the Medical Society of the State of New York, aged 82, died, April 11

Albert B Walker Ⓢ Wyandotte Mich., Detroit College of Medicine, 1899 aged 64 on the staff of the Wyandotte General Hospital, where he died, April 11, of carcinoma of the intestine

Charles Sumner Wiseman, Union Mills Ind., Fort Wayne College of Medicine 1905 formerly county health officer served during the World War aged 58 died, April 25 of uremia

Charles W Horton, Hiwasse, Ark Barnes Medical College, St Louis, 1900, member of the Arkansas Medical Society, aged 65, died, April 28, of acute dilatation of the heart

Frank Ware Smith, St Thomas, Ont, Canada, M B, University of Toronto Faculty of Medicine, 1894 and, M D, Trinity Medical College, Toronto, 1894, aged 66, died, April 24

Burdett Sheridan Adams, New Haven, Conn Hahnemann Medical College and Hospital of Philadelphia, 1898, aged 64, died, April 2, of cerebral hemorrhage and arteriosclerosis

James Arthur Clement, Dillsburg, Pa., Southern Homeopathic Medical College, Baltimore, 1894, aged 65, died, April 30, of cerebral hemorrhage, and arteriosclerosis

Robert F Strayer, Pittsburgh, Hahnemann Medical College of Philadelphia 1881, aged 76, died, April 28, in the Homeopathic Hospital, of coronary thrombosis

Archibald Rowan McCracken, Seattle Detroit College of Medicine, 1901 aged 67, died, April 24, as the result of injuries suffered in a fall several months ago

Edmund Peaslee Douglass Ⓢ Gales Ferry, Conn University of the City of New York Medical Department, 1889, aged 71, died April 9, of lethargic encephalitis

Frank Deming Solley Ⓢ Bethel, Conn., Columbia University College of Physicians and Surgeons, New York, 1905, aged 69, died, April 24, of pneumonia

David Stevens, Okmulgee Okla., College of Physicians and Surgeons, Keokuk, Iowa, 1880, aged 83, died, April 12, of arterial hypertension and uremia

Robert R Walker, Oklahoma City, Tulane University of Louisiana Medical Department New Orleans 1885 aged 72 died, April 24, of angina pectoris

Walter C Welch, Caddo Mills Texas Texas Medical College and Hospital, Galveston, 1881, justice of the peace, aged 78, died, April 11

Robert Arthur Thomas, Magdalena, N M., Louisville (Ky.) Medical College, 1904, aged 58, was killed, April 24, in an automobile accident

Lars Thomas Wendelboe, Newark, N J Baltimore Medical College, 1895, aged 70, died, April 23, of carcinoma of the sigmoid

Adolph Carl Adam Gaul Ⓢ Olympia Wash Rusch Medical College, Chicago 1900 aged 77 died April 26 of pneumonia

Hiram H Wirt, Santa Monica, Calif., University of Wooster Medical Department Cleveland 1872, aged 87 died April 3

James Benson Whitely, Goderich Ont Canada Victoria University Medical Department Coburg 1882, died April 12

John Wesley Ward, Titusville Fla College of Physicians and Surgeons Keokuk, Iowa, 1880, aged 83, died, April 9

S W Stiles, Atlanta Ga Atlanta Medical College, 1885, aged 78 died, April 12 of cardiovascular renal disease

Frank Joseph Woitishek, Los Angeles, Chicago Medical College 1890 aged 72 died April 19

Correspondence

"THE CLINICIAN AND THE SEROLOGIC TEST FOR SYPHILIS"

To the Editor—In the editorial "The Clinician and the Serologic Test for Syphilis" (*THE JOURNAL*, July 10, p 134) appears the following sentence "If the tests are negative there is a 95 per cent chance that the patient does not have syphilis (in the absence of previous treatment), but a negative result does not exclude the diagnosis." This statement as given in the editorial may be somewhat misleading. The incidence of syphilis in the general population ranges from 1 to 20 per cent depending on the race, and social and economic conditions. In the average white population taken at random, the incidence of syphilis is about 5 per cent. Hence the chance that any white individual, taken at random, does not have syphilis is 95 per cent.

As is pointed out in the editorial, "in untreated syphilis the range of positivity of the five tests named is from 90 to 95 per cent in all stages of the infection." Hence only about 5 per cent of syphilitic individuals in the general population (excluding treated cases) will give negative results, so that 5 per cent of 5 per cent, or only 0.25 per cent of the people in the general population giving negative reactions, will have syphilis. Hence if the tests are negative there is a 99.75 per cent chance that the patient does not have syphilis, not a 95 per cent chance, as is stated in the editorial.

Of course, these calculations are based on hypothetical percentages which have been assumed for purposes of illustration.

A S WIENER, M.D., Brooklyn

REMOVING ADHESIVE TAPE

To the Editor—Your recent editorial on methods of removing adhesive plaster from the skin, and rumors of a damage suit for injuries attributed to violent removal, lead us to suggest oil of wintergreen as a simple, painless and highly efficient means. The oil should be applied with a very small cotton swab only to the point of separation of the adhesive from the skin. If it is applied to the external surface of the plaster the fabric will come away, leaving the adhesive material adhering to the epidermis.

TOXIC DRUGS

To the Editor—With regard to the article in *THE JOURNAL* on "Dinitrophenol and Desiccated Thyroid in the Treatment of Obesity," by Dr. Samuel Simkins (June 19, p 2110, June 26, p 2193), I wish to express my appreciation of the high quality of the reprint. In the concluding paragraph in the summary the recommendation is made that "the indiscriminate clinical use of dinitrophenol should be discontinued until the vexing problem of cataracts complicating dinitrophenol therapy is solved." I would suggest that at the present time the profession follow it, omitting the adjective "indiscriminate." The great trouble is that we are not able to discriminate. Is it not enough to know that the drug is extremely toxic and that we should not employ it in the treatment of obesity?

Recently an article appeared in a Mayo Clinic publication stating that the authors used cinchophen in the treatment of gout. Of course, they use careful liver function tests before prescribing the drug, but the point that I wish to make is that the average physician may take a chance without making the test for liver function. The question of the toxicity of the drug appears to be clearly answered in the article by Palmer and Woodall in the Sept 5, 1936, issue of *THE JOURNAL*.

Certainly enough incriminating evidence has accumulated in the literature to exclude this drug from the pharmacopeia.

Phenolphthalein is a drug that is largely used as a habitual laxative. Its popularity is due to the fact that it acts and is usually prepared in convenient palatable form. In certain individuals the drug is extremely toxic, producing skin eruptions and other evidences of toxemia. I make it a rule in my practice to examine the feces carefully in every case that comes to the clinic. The patients who have taken this drug for any length of time present evidence of chronic catarrhal enterocolitis. The drug belongs to the class of cathartics that produce local irritation. Many of the manufacturers of agar and oil mixtures slip in a dose of phenolphthalein to make the preparation more active, thereby deluding the doctor, who believes that he is prescribing a nonirritant mixture.

HORACE W. SOPER, M.D., St. Louis.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TEST FOR ALCOHOL IN BLOOD AND BODY FLUIDS

To the Editor—In a recent issue of *THE JOURNAL* appeared an inquiry regarding the test for alcohol in the blood or other body fluids. This was answered but not with sufficient detail. You mention potassium dichromate change of color test. Can you supply information as to the strength of the solution and the conduct of the test?

J. B. DONALDSON, M.D., Lorain, Ohio.

ANSWER—A great variety of tests for alcohol in the blood and other fluids are described in the literature, and the majority of them depend on the color change produced in potassium dichromate solution when reduced with alcohol. Abels (*Pr. Soc. Exper. Biol. & Med.* 34:346 [April] 1936) has described a simple modification of the Widmark test that is sufficiently accurate for clinical purposes. The technique is as follows:

One cubic centimeter of 0.33 per cent potassium dichromate solution in sulfuric acid (made by dissolving 333 mg. of potassium dichromate in 1 cc. of water and diluting to 100 cc. with concentrated sulfuric acid) is spread on the bottom of a 50 cc. Erlenmeyer flask. Five-tenths cubic centimeter of blood or other fluid supposed to contain alcohol is pipetted onto a specially prepared bit of filter paper and suspended over the potassium dichromate-sulfuric acid mixture. The flask is heated at 100 C. for from fifteen to thirty minutes. After cooling, the contents of the flask are made up to 3 cc. with distilled water. This will require about 17 cc. of water (1 cc. of the potassium dichromate-sulfuric acid solution + about 0.3 cc. extracted from the unknown solution + about 17 cc. of distilled water). This mixture is placed in a test tube (6 inches by one-half inch) and is compared with the standards.

Fig. 1—Piece of filter paper cut out

Fig. 2—Portion B rolled & secured by tying

The standards are prepared as follows. In each of five test tubes (6 inches by one-half inch) is placed 1 cc. of the potassium dichromate-sulfuric acid solution. In the first of these tubes is added 2 cc. of distilled water. In the second is added sufficient alcohol to represent a concentration of 0.05 per cent. In the third enough alcohol to represent a concentration of 0.10 per cent. In the fourth, a concentration of 0.15 per cent, and so on, until the last tube represents a concentration of 0.5 per cent. All the standards are brought up to a total of 3 cc. each by the addition of distilled water. The standard tube is now heated to 100 C. for ten minutes. Now by comparing the color of the unknown solution with the standards, the con-

tration of alcohol in the unknown may be determined. The standards, if well sealed and protected from light, will remain accurate for two weeks. The first standard tube will represent a concentration of 0 per cent alcohol and the last a concentration of 0.7 per cent, with 0.05 per cent gradations lying between.

An ordinary piece of filter paper is cut out as shown in figure 1. Portion B is rolled up as shown in figure 2 and secured by tying. The fluid to be examined is pipetted onto portion B. The paper is inserted into the flask so that portion B is suspended over the potassium dichromate-sulfuric acid solution and held in position by securing portion A between the side of the flask and the stopper.

DIAGNOSIS AND TREATMENT OF CONVULSIONS IN INFANCY

To the Editor—A boy aged 15 months with threatened convulsions of which he has had twelve attacks within the past six months is unconscious. The eyes are closed. There are occasional twitches of the arms and legs. The most alarming symptoms are the slow and irregular respiration with evident expiratory effort. Mucus collects at the lips and larynx. There is no cyanosis. First cousins are said to have had convulsions and to have outgrown them. For infantile convulsions Holt recommends cold to the head and counterirritation to the skin and in addition chloroform chloral by rectum and morphine and magnesium sulfate subcutaneously. In such a case as described would the chloroform and other drugs be indicated?

H A HASKELL MD Windsor Calif

ANSWER—From the description furnished in the query it is evident that the slow and irregular respiration, with expiratory effort, indicates increased cerebral pressure associated with convulsive seizures. It is obvious that a careful neurologic examination is indicated. Various clinical tests should be made to exclude a possible tetany. The eyegrounds should be examined in order to detect a possible choked disk or optic atrophy. The reflexes and nerve signs should be examined so far as possible in a child of this age. In view of the diminished respiratory rate, a lumbar puncture would seem to be indicated during the attack, not only for the purpose of relieving intracranial pressure but also for the information that might be obtained by a chemical and microscopic examination of the cerebrospinal fluid.

As far as the use of chloroform is concerned the hazard is so great and the effect of such short duration that one would hesitate to administer it. In an infant who presents alarming symptoms on account of slow and irregular respirations, one would consider that the use of morphine might further depress respiratory movements and, on theoretical grounds at least, the morphine would seem to be contraindicated.

Magnesium sulfate subcutaneously is particularly indicated in the convulsive seizures associated with tetany. On the other hand, it is also supposed to act by dehydrating the brain and diminishing cerebral edema. While chloral hydrate acts slowly, it is relatively safe if given by mouth or rectum in proper dosage. Would it not be better to try to prevent the occurrence of the attacks by giving small doses of phenobarbital or bromide in the interval between the seizures for a prolonged period?

ISOLATION HOSPITAL FOR CONTAGIOUS DISEASE

To the Editor—As chairman of a committee of the Uniontown Hospital Staff to investigate the advisability of establishing an isolation unit for contagious diseases I am writing you for some information. I should like to know if this type of unit in a town of 20,000 with one hospital with a bed capacity of 225 is usually part of that type of hospital. Is this type of unit where it does exist supported by the hospital as a unit of the hospital or by the city or county? What is the number of beds advised for this size hospital and city? Do you have any plans for this type of unit that we could inspect? I would appreciate your giving me this information and any other information that you feel would be of value to us along the line of this survey. Any plans, reprints or outlines that you might have will be carefully handled and returned if sent to us.

JOHN D. STURGEON JR., Uniontown Pa

ANSWER—The question of establishing an isolation unit for contagious diseases in a relatively small city is always a difficult one to settle. There are times when availability of beds for contagious diseases seems absolutely essential and yet there are other times when a hospital, which would be inadequate during an epidemic would be a white elephant because it would be empty and would be piling up overhead costs to no good purpose. Flexibility is the quality in contagious disease bed capacity which is most to be desired. This is difficult in a separate hospital unit which requires all the administrative facilities including laundry, kitchens, cleaning, supervision and other items of overhead. It is most easily achieved in connection with a general hospital where the supervisory and service department can be extended to cover the contagious disease

unit. It has been demonstrated that it is quite possible to conduct a contagious disease unit as a part of a general hospital, provided the necessary isolation of personnel and equipment is carried out completely. Such affiliation with the general hospital affords many advantages, including not only the extension of supervisory and service departments of the hospital, through the service of the contagious disease unit, but also the consultation facilities of the hospital staff and the ability to run the contagious disease unit in such a way that physicians sending patients to the contagious disease hospital will not be compelled to turn them over to the care of staff physicians but will be able to care for their own patients themselves, to the greater satisfaction of the family, the patient and the physician. The number of beds advised for the city in question would be difficult to estimate. As stated, there might be times when 100 beds would be needed and other times when none would be needed. A hospital of fifty beds has proved ample for a city of 70,000 population. This, however, was a city hospital and no patients from outside were taken except under unusual circumstances. In estimating the needs, one would probably want to consider not only the population of the town but the population also of the surrounding country from which the general hospital draws its clientele. If arrangements could be made so that there would ordinarily be available from ten to fifteen beds, this would serve most needs except during epidemics. One would, of course, have to draw the line against hospitalizing certain cases such as measles, whooping cough, chickenpox and minor contagious diseases unless complicated by conditions which in themselves demand hospitalization. One would also have to make separate provision for smallpox, since this disease is difficult, if not impossible, to house in connection with a general hospital. As for plans the only thing we can suggest is that a hospital must be planned to meet the needs of the community after a careful study of those needs. We would not advise the adoption of any ready-made plans any more than we would advise the adoption of a plan out of a magazine for a house for one's own personal residence. Satisfaction in building a hospital can be expected only under the immediate supervision of a competent hospital architect who will give careful personal attention to the needs of the situation and will then make his plans to meet those needs.

TREATMENT OF CLIMACTERIC

To the Editor—My wife aged 48 is having a hard time going through the menopause. She is depressed, cries easily, is irritable, has days when she feels fine and others when she is suspicious, is quarrelsome and feels that the whole world is antagonistic. I have been giving her injections of theelin in oil 2,000 units about once weekly. She has to take sedatives almost every night to sleep. I am wondering whether you have any suggestions or if there is anything new which I might use to help this trying period and make it easier for her. Would x-ray treatment of the ovaries be of any benefit or would it be harmful? I would appreciate any information you may have on the mental disturbances of the menopause. Please omit name.

MD Oklahoma

ANSWER—The age of the patient and her symptoms are typical of the menopause. There are about eighteen or twenty symptoms that are complained of at this period in life. They are classified as nervous, circulatory and general. The subjective nervousness, depression and hot flushes are the ones that cause the most discomfort. It is well to remember that cessation of menstruation is not the end of this condition but that it is only a visible evidence that disturbance of function of the endocrine glands is present which involves especially the ovaries, the anterior pituitary, the thyroid and the adrenals which disturbance in turn involves the delicate equilibrium that normally exists between the two divisions of the autonomic nervous system. The object of treatment is to assist in maintaining a more normal endocrine balance until such time as a normal glandular adjustment will occur.

The duration of the climacteric may vary from a few months to five or six years and the severity of the symptoms from practically none to involutional melancholia.

The patient has some moderate psychotic symptoms which, if they become worse, must be classified as involutional melancholic.

Treatment should consist of theelin or other equally potent estrogen in oil 2,000 international units every other day until she shows definite improvement (absence of depression and psychosis), then give 1,000 international units intramuscularly three times a week for from one to two months and if improvement continues gradually taper off the dosage. If symptoms should recur some time after the cessation of treatment it should be reinstituted. Along with injections it is well to give the patient effective dosages of mild sedatives four times a day, such as chloral hydrate elixir of phenobarbital and sodium

bromide, to quiet the nervous system, until the endocrine treatment becomes effective. Some hypnotic tablet may be given at bedtime for sleep for the same reason.

Röntgen treatment of the ovaries to inhibit or destroy their function is unnecessary, for the ovaries are hypofunctioning at present and there is a possibility that the ovaries might have some other activity besides graafian follicle development and ovulation.

Be patient and persistent with the treatment and considerate of the patient, for she is physiologically ill.

One must be sure that there are no other ailments, for the patient must be treated as a whole and not as an aggregation of glands.

PROGRESSIVE ANKYLOSING SPONDYLITIS

To the Editor—Since April 1936 I have had under observation a case which has caused me considerable concern. A man aged 27 married 5 feet 10 inches (178 cm) in height weighing 140 pounds (63.5 Kg) originally complained of pain in the sacro-iliac region with associated sciatica, with a possible history of injury some three years previously. The teeth and tonsils had been removed, the nose ears and eyes were normal, there was no evidence of infections in the sinuses or abdomen, the prostate was negative to special examination. A flocculation test was negative. The urine was normal. The sedimentation rate at one hour was 99 mm. X-ray examination of the chest was negative. X-ray examination of the spine showed a slight dorsal scoliosis with a marked hypertrophic change in the sacro-iliac region with complete obliteration of the right joint and partial obliteration of the left. The heart and lungs were normal. The entire physical examination was negative with the exception of some restriction of motion in the sacro-iliac region. The neurologic examination was entirely negative. Hemoglobin was 85 per cent, white blood cells numbered 16,000, red blood cells 4,500,000. The differential count was normal. The Wassermann and Kahn reactions were negative. The Widal test was negative. Agglutination tests for *Bacillus paratyphosus* A and B, *Brucella melitensis* and *Bacterium tularensis* were all negative. A course of Clossen and Wetherby's vaccine was given without any benefit. A sacro-iliac belt gave moderate relief for a time. A Baer manipulation was attempted for relief of the sciatica and was moderately successful. Later the patient developed severe muscle cramps in the abdominal muscles as well as in the muscles of the chest and the legs and thighs. He was given ten injections of 10 cc of 10 per cent calcium gluconate which gave considerable relief to the cramping of the muscles. He was examined by the Mayo Clinic and a course of intravenous injections was suggested. He had a slight chill from the first injection and about two hours quiet sleep from the remainder of the injections. His hemoglobin had dropped to 52 per cent at this time and he was given a three weeks course of ventriculin and iron and the various vitamin concentrates, which increased the hemoglobin to 75 per cent. After the treatment was stopped it immediately dropped in a few days to 52 per cent with white blood cells 16,000, red blood cells 4,500,000 and differential negative. At this point he was started on a course of Compolon injections and has had two of them to date. At present his neck is stiff and he stoops forward about 10 degrees although x-ray examination of the cervical spine is negative. My diagnosis of chronic infectious spondylitis was confirmed by the Mayo Clinic. Any suggestions that you can offer as to where I might find the foci of infection in this case or any therapy you may suggest as offering some hope for keeping up the hemoglobin or something that might offer some relief from the constant pain and spasms would be greatly appreciated. At no time has he been disabled from work of a clerical type although I marvel at how he can continue it in his present condition. His best friend as he puts it is Empirin Compound which he takes on an average of 30 grains (2 Gm) daily for the partial relief of pain. Any suggestions you may offer will be greatly appreciated.

C KENNETH COOK M.D. St Paul

ANSWER—This detailed description of the symptoms and signs of progressive ankylosing spondylitis in a young white man is compatible with a diagnosis of Strumpell-Marie's disease. This author called the condition rhizomelic spondylitis because of the characteristic progressive involvement of the spine (including the sacro-iliac joints) and one or more "root" joints (hip or shoulder) and comparative to complete freedom in other appendicular articulations. Both Strumpell-Marie and later contributors on this subject have thought that a low grade infection was the etiologic factor, but this has never been proved to be true. The gonococcus was early under the greatest suspicion, but this hypothesis remains unconfirmed, if not actually disproved. Typhoid carriers (the gallbladder is usually then the focus) have been known to develop a similar progressive ankylosing spondylitis. Treatment has been varied and has included everything ever suggested by those who treat arthritis. Neither removal of all possible foci nor any therapy has been successful in arresting the progress of the disease. The prognosis, if the diagnostic impression proves to be correct, is always ankylosis of the spine and sacro-iliac joints, probably of one or both hips and possibly of one or both shoulders. The average course of the disease is about five years. When ankylosis is complete and the disease has "burned itself out" there will be little if any pain and the degree of disability will not only depend on the number of joints ankylosed but will also determine the effectiveness of orthopedic measures,

which should always be carried out during the active phase of the disease. These measures are undertaken to hold the spine in the erect position and the root joints that may be involved splinted in a position to make possible maximum function when and if ankylosis occurs.

In addition to the therapy outlined for the anemia, a high caloric diet having a high content of milk or milk products should be given, reinforced with concentrates containing vitamins A, B, C and D.

X RAY DOSAGE

To the Editor—With a 30 milliamperage radiator type Coolidge tube at 12 inches distance without filter 3 milliamperes is used for three minutes. What part of an erythema or skin unit dose is developed considering the skin to be normal? In terms of milliamperage time what is considered an erythema dose? Please omit name.

M D Iowa

ANSWER—The question, as asked, is unanswerable, for the correspondent does not give any of the voltage factors. Unless one uses a recording roentgen dosimeter, one must know and use the following factors in determining x-ray dosage: voltage, milliamperage, distance, filter and time. The omission of any of these factors makes it impossible to calculate the dosage.

Assuming that the voltage used is 100,000, a test was made at this voltage with a currently employed Snook machine a 30 milliamperage tube, at 12 inches distance from focus of tube to skin, using 3 milliamperes for three minutes. The dosage (in air) delivered was 180 roentgens, which is about 60 per cent of an erythema dose if delivered at one sitting, the skin assumed to be normal.

Unless an instrument has been carefully calibrated by a competent scientist with proper measuring instruments, it is unscientific and dangerous to attempt to state an erythema dose in milliamperage-minutes.

ACUTE ORCHITIS

To the Editor—A white boy aged 15 years who is perfectly sound physically and normal in all respects had a swelling of the right testicle Nov. 11, 1936 when I first saw him. The testicle was about 25 per cent larger than the left testicle. The involvement apparently was not in the epididymis but distributed throughout the testicle. He had a temperature ranging between 100 and 103 F for five days at which time the swelling in the testicle had subsided and the temperature was normal. The boy had been playing football and I assumed that he had been injured in this testicle. However the same thing occurred in the left testicle on December 18. The clinical course was about the same as with the right side. The vas was not enlarged or tender. The prostate was normal. The seminal vesicles were equal in size and at no time was pus found in the urine. The white blood cell count on two occasions was 9,000 with a normal percentage of neutrophils. Jan. 4, 1937 the left testicle again began swelling and he was found to have a temperature of 101 F. The physical condition was the same as has been outlined before. January 8 the swelling had subsided and the temperature was normal. I would appreciate any information that you might give me in making the diagnosis in this case. Please omit name.

M D Georgia

ANSWER—The correspondent has apparently ruled out any involvement of the epididymis. The discussion can be limited to the acute lesions of the testis proper. Of these the first to be discussed will be acute orchitis.

Acute orchitis may be either an ascending type of infection from the posterior urethra by way of the lumen of the vas through the epididymis—epididymo-orchitis—or metastatic and as such is not an uncommon complication of many acute infectious diseases. Of these the one that most frequently produces orchitis is mumps. Acute orchitis also has been noted in typhoid as well as in paratyphoid fever, influenza, diphtheria, scarlet fever, acute tonsillitis, and many others. On the other hand, an attack of acute orchitis may be due to the presence of a focus of infection in other parts of the body, such as an abscessed tooth, an infected sinus or furunculosis. The correspondent does not state whether or not the patient recently had one of the acute infectious diseases, which may have preceded the acute involvement of the testicle, and this is important, of course. Perhaps the patient had some transient infection that was not recognized and in an epidemic of influenza such as the recent one epididymitis, pyelitis and prostatitis have followed in the wake.

Finally, it is necessary to direct attention to a condition that is frequently overlooked or not considered in the differential diagnosis—torsion of the testicle (or, more correctly, torsion of the spermatic cord), a condition caused by sudden twisting of the cord so that the blood supply to the testicle is shut off. This condition is often mistaken for acute orchitis and acute epididymitis. Although the cases are generally associated with a history of straining (football, baseball, wrestling, rough housing), cases have been recorded in which the torsion occurred

in the night while the patient was sound asleep. As a rule, cases of torsion are unilateral.

The absence of a history of trauma, especially preceding the involvement of the second testis, would lead one to suspect that the orchitis is metastatic in origin.

BILATERAL EDEMA OF ANKLES

To the Editor—What do you believe is the cause of bilateral edema of the ankles in a man of 72 whose heart is normal except for a mild mitral systolic apical murmur and extrasystoles at irregular intervals? The edema has been present for about four months being less in the mornings. The murmur, extrasystoles and rapid pulse (80) have been present to the patient's knowledge for at least thirty years. The blood pressure is 140 systolic 74 diastolic. There are a few varicose veins in both legs which have been injected with quinine hydrochloride urethane during the last month without any appreciable difference in the edema. Digitalis 1 cat unit daily has been used for five weeks in the hope that it may relieve the swelling of the ankles. The kidneys apparently are normal. There is no nocturia or abnormality in the urine. The edema at times extends up to the knees when the patient is on his feet a great deal. Physical examination is essentially negative otherwise. What else could be done in this case? Please omit name. MD, California

ANSWER—In making the following suggestions it is assumed that there is no mechanical obstruction to the return flow in the extremities. Such obstruction might be caused by an old thrombophlebitis, a lymphangitis with chronic induration or even the varicose veins. Apparently this is not a renal edema. At the age of 72, cardiac edema is by far the most common. With the details as given at hand one suspects a mild cardiac failure probably due to degenerative heart disease. Based on this assumption the following suggestions are offered.

Digitalis should reduce a cardiac edema unless the heart is incapable of responding. This does not seem likely in the present instance. One cat unit equals about 0.1 Gm. of powdered leaf. This is a rather small daily dose unless enough of the drug was given previously to insure the optimal digitalis effect. After the optimal response is obtained it may often be maintained with 1 cat unit daily. In this case the dose might be cautiously increased to 2 units (0.2 Gm.) or even 3 units (0.3 Gm.) daily for a time. In view of the frequent extrasystoles, careful watch should be maintained for signs of increased cardiac irritability.

The purine base diuretics theobromine and theophylline compounds are said to cause an improved cardiac action. Whether or not they have a local action on the kidney is a subject for argument, but at any rate they frequently cause a diuresis that is of value in reducing edema.

The acid base salts ammonium nitrate or ammonium chloride, 2 Gm. three or four times daily, will often bring about a considerable diuresis. They are not well tolerated by the stomach and should not be continued over too long a period.

The mercurial diuretics salyrgan or mercupurin given in doses of from 0.5 to 2 cc. intravenously or intramuscularly, frequently produce a profound diuresis. The mobilization of fluid is enhanced if the acid base salts are given for three or four days preceding the injection of the mercurial.

SCHILLER TEST FOR CANCER OF CERVIX

To the Editor—Will you be so kind as to inform me of the name of the test for cancer of the cervix by the topical application of iodine and give a brief outline of the procedure and reading of the test?

J. M. KERCHEVAL M.D., Wolcottville Ind.

ANSWER—The test for cancer of the cervix to which the correspondent refers is known as the Schiller test.

Schiller Walter. Early Diagnosis of Carcinoma of the Portio Uteri. *M. J.* 26: 269 (Nov.) 1934.
Zur Frühdiagnose des Karzinoms der Portio uteri. *Monatsschr. f. Krebsbekämpfung* 2: 7 (Jan.) 1934.

It is preferable to use Gram's solution, consisting of 1 Gm. of iodine and 2 Gm. of potassium iodide in 300 cc. of water. The use of this dilute aqueous solution of iodine results in sharper differentiations than does ordinary compound solution of iodine. The procedure for staining is as follows. After the cervix is fully visualized by means of a bivalve speculum it is thoroughly dried and inspected and from 20 to 30 cc. of Gram's solution is poured into the vagina. The excess solution is removed by means of a cotton pledget. The normal cervix should be stained evenly a dark brown. Pathologic lesions fail to take the stain and stand out as sharply demarcated yellowish areas.

The test depends on the affinity for iodine of glycogen present in the epithelium of the portio. The normal squamous epithelium of the cervix contains glycogen in varying amounts depending on estrogenic activity. Pathologic areas and par-

ticularly carcinoma cells do not contain glycogen and therefore fail to be stained by iodine. In evaluating the Schiller test, one must have some experience. About four out of five patients who present themselves for examination will have a negative test, in which case the entire surface of the cervix has stained evenly. These patients do not have carcinoma of the portio of the cervix. The areas that fail to stain may or may not represent early carcinoma. In practice it has been found that only 15 or 20 per cent of these areas are malignant. An erosion of the cervix will not stain with iodine and will remain slightly reddish. In the earliest stages an erosion consists largely of cervical epithelium, which is not affected by iodine. It is probably good practice and the safest procedure to take a biopsy and submit to microscopic examination bits of tissues from all areas that do not stain. Superficial areas can be best removed with a sharp spoon curet, but one must attempt to include the transition zone between normal and pathologic epithelium.

The Schiller test is of value only in squamous cell carcinoma of the cervix. The existence of adenocarcinoma of the cervical canal or of the corpus must not be overlooked. These must be ruled out by probing the cervical canal and by dilation, curettage and a microscopic examination of the curettings.

RABIES

To the Editor—Here in Louisiana we are experiencing the usual mad dog scare. Public officials of small cities including veterinarians supplemented with the propaganda of manufacturing firms find it to their interest to impress the public with their efficiency. Veterinarians not unlike doctors advise shots based only on hygienic reports of serum manufacturers and resort to oppressive measures to stamp out the so-called rabies epidemic. Right now in this county besides restrictions placed on dog owners by city officials the police jury of the parish (county) has passed an ordinance requiring all dog owners to take their animals to a public clinic to be held at various points in the county just as cattle owners are compelled to take their stock to public dipping vats for the cure of ticks. In such measures the small city or town newspapers cooperate with these officials with sensational headlines and stories of many dogs running amuck and biting children and stock. And yet a human case of hydrophobia is rarely heard of. In the last few weeks dogs heads have repeatedly been sent to the Parish Health Clinic and I have yet to hear of one that was not a reported positive for hydrophobia. What is the present scientific status of the one injection preventive and curative antirabies serum as applied to dogs? Is it not a fact that many dogs have developed rabies after one of these live virus single injections? Are Negri bodies on which the diagnosis of rabies in animals is dependent (the specific germ never having been isolated) now considered infallible proof of rabies? Are they sufficiently easy to discover as to make examinations by ordinary bacteriologists not specially skilled conclusive? Concerning Negri bodies Dorland's Medical Dictionary 1935 says: 'Oval or round bodies seen in protoplasm and sometimes (italics are mine) in nerve cells of animals dead of hydrophobia. The fact that the word sometimes is used would seem to indicate that bacteriologists are not always able to make a diagnosis even when competent and the animal has actually died of hydrophobia. I have been engaged in promoting and breeding a famous breed of dogs for forty years continuously and uninterruptedly in these four decades I have never passed a single year in which I did not exhibit the dogs as a gentleman's sport. In all this time I have never known or heard of a professional handler or exhibitor having hydrophobia from being bitten and many of these professional handlers who make the circuit of dog shows profitable in handling the animals of wealthy sportsmen do not believe there is any such disease as hydrophobia. Of necessity they are frequently bitten by dogs they have taken under their care. It is a fact that some able veterinarians deny the existence of this malady. I do not agree with this but I do doubt the safety and advisability of these single live virus injections. For years epidemics of running fits have been existent all over the dog world and the cause is unexplained. I have seen it go through my kennels repeatedly. Young high bred dogs under excitation or physical exertion suddenly run wild barking and yelping violently seeking some dark corner hole or cellar in which to hide. Within half an hour the malady subsides the animal is dull and stupid and recovers and in the next day or two the process may be repeated. This is sufficient to inspire the cry 'mad dog!' and for the newspapers and the small vested interests to do the rest.

FAYETTE C. EWING M.D. Alexandria La.

ANSWER—Rabies in dogs is subject to periodic waves of increase in different regions. Only recently an extensive outbreak occurred in Chicago. Many persons were bitten and deaths from human rabies occurred. In connection with this matter the following statement in the review for 1936 by the president of the Rockefeller Foundation is highly significant.

'In 1936 the Foundation began laboratory and field work in relation to rabies, which has become an increasing menace, particularly in some of the Southern states. Little has been done on this disease since Pasteur's day and it is hoped that a quicker and more positive test for rabies in animals may be developed and perhaps a less cumbersome method of vaccination.' The very best that can be said for the one injection of antirabies vaccine is that it is still no further than in the experimental stage. Whether many dogs have developed rabies after the injection of live viruses is extremely difficult to determine, but that possibility cannot be denied. Negri bodies

are sufficiently characteristic to be regarded safely as diagnostic, but the examination of suspected cases, like all examinations of such nature in general, are of course reliable only in competent hands

SPERMATORRHEA

To the Editor—A white man aged 21 single has noticed a "milky color to the urine intermittently for the past ten months. He experiences no pain on urination but is troubled with frequency during the daytime. These episodes of milky urine occur about twice a month. The urine is clear for a few moments on these occasions and suddenly the stream changes to a thick white color. There is no discharge present before or after these bouts. I have examined the urine on two of these occasions and found the milky fluid loaded with live sperm. No pus cells or any other organisms were present. Prostatic smears have been repeatedly negative as have the specimens of urine between the spells. The patient has never had gonorrhea or any other prostate disease. His physical examination is essentially normal. Blood Kahn and Hinton reactions are negative. The genitals appear normal in development. The condition has caused the patient a great deal of mental concern. I would appreciate any information as to the etiology of this unusual condition and also what measures I might take to overcome these episodes. Please omit name

MD Maine

ANSWER—The condition is occasionally seen in young persons who are not married, it is called spermatorrhea and as far as we know is of no clinical significance. In a certain few individuals there is an apparent laxness in the ejaculatory ducts, allowing an occasional emptying of the seminal vesicles into the prostatic urethra. As noted in the present case, the secretion gives a milky cast to the urine and on microscopic examination shows nothing more than vesicular secretion and live sperm cells. The condition has no clinical significance and as far as is known there is no indicated treatment. In almost all instances the spermatorrhea will disappear following the marriage of the individual, with regular emptying of the seminal vesicles. The only treatment is the reassurance of the patient

DISCOLORATION BY BLOOD IN PATHOLOGIC SPECIMENS

To the Editor—Kindly give me the best method for the removal of the discoloration caused by blood in specimens preserved in 10 per cent solution of formaldehyde. Is there any method or solution which may be used at first to obviate this discoloration? I have a number of fetuses which are very dark. Would it be possible to apply the Spalteholz method of clearing to such material? I have been unable to find any references in English to this method. Kindly omit name

MD Michigan

ANSWER—Much of the discoloration caused by blood in specimens preserved in solution of formaldehyde is due to reduction of blood pigments by the formaldehyde. Immersion of such specimens in solution of hydrogen peroxide, preferably in sunlight for from one to two days will remove much of the brown discoloration. If fetuses are preserved in Kaiserling solutions in the regular way and not left in Kaiserling I too long much discoloration will be prevented.

As part of the Spalteholz method of clearing involves the bleaching of specimens in peroxide, it is probable that Spalteholz's method of clearing will give good preservation even with discolored fetuses. A satisfactory method of utilizing the Spalteholz principles is the following

- 1 Fix in 10 per cent solution of formaldehyde
- 2 Bleach with solution of hydrogen peroxide in sunlight for two days
- 3 Dehydrate with 70 per cent ethyl alcohol one day, 95 per cent ethyl alcohol one day and 100 per cent ethyl alcohol one day
- 4 Place in benzene for one or two days
- 5 Place in methyl salicylate full strength
(There will be air bubbles at this stage, pump out in a vacuum for from two to three hours) Store in methyl salicylate

WORD BLINDNESS

To the Editor—Please give me some information about the latest treatment in word blindness

B M HOWLEY MD New Brunswick N J

ANSWER—The latest treatment in word blindness aims at overcoming the difficulties created by the perceptual peculiarities of the patient. In learning to read, emphasis is placed on auditory and kinesthetic types of stimulation. Phonetic rather than visual methods are used in the teaching of reading with such children. Kinesthetic methods involve the tracing of letters sometimes the use of letters cut out of wood so that actual contact can also be used in becoming familiar with shapes and forms of letters. Considerable effort at times must be expended in overcoming the tendency to reverse images. The

devices that aid the child in following the printed material in the proper direction are used. For some children, when disturbances in the eye movements can be demonstrated such mechanical devices as the mentronoscope are used to improve ocular coordination and to speed up the rate of reading. Often the psychologic problems produced by the disability are more difficult to overcome than the mechanical effect of the disability. The discouragement and anxiety that children develop on account of their inability to read may result in a tremendous resistance to learning to read at all. This may have to be overcome before progress can be made in teaching them the mechanics of reading.

See "Children Who Cannot Read," by Marian Monroe, University of Chicago Press, 1932

NEUROLOGIC SYMPTOMS DUE TO TRAUMA OR ARTERIOSCLEROSIS

To the Editor—Dec 5 1935, my patient was working on the county highway with a gang of men digging rock from the side of the road. A piece of earth weighing over 200 pounds fell on him pinning him to the ground. He sustained a fracture of both bones of the lower right leg just above the ankle. He was brought to the hospital where the parts were molded properly and a plaster cast applied. The man was in this cast for about ten weeks. The cast was removed frequently during the last weeks to massage and inspect. He got up on crutches and was able to go out as well as to the compensation board for examination. Suddenly he began to complain of pain in the lower part of the back, lack of strength and difficulty in getting about. He insisted that he could not use his crutches and had to go to bed. He was given massage for his back. He had slight secondary anemia. He had weak muscular coordination in the hands and legs slurring of speech intestinal cramps and impaired sensation of the skin. He was brought to the hospital about March 1 1936. He became progressively worse until about the last of July. Then he had to be taken to the state hospital because he was unmanageable in the local hospital. He died there after about two weeks. Could this man have had a marked accentuation of an admitted (arterio) sclerosis to such a degree that his spinal cord and nervous system degenerated so rapidly all on account of the accident he suffered in December three months before he started to show the spinal symptoms? Was the spinal breakdown directly caused by his injury? The Wassermann reaction of the blood was negative and the urine was normal. He had been a drinker to some degree but never to interfere with his working regularly. Have you any suggestions about trauma and spinal cord injury coming on late especially in relation to arteriosclerosis?

E L FINLEY MD Oneida N Y

ANSWER—It is quite possible that an injury as severe as the one described may have precipitated the symptoms resulting from a condition which prior to the accident had not yet reached a definite clinical stage. There is no evidence to show, however, that an accident of this type could in itself have been the sole etiologic factor in the bringing about of a generalized neurologic syndrome which involved speech, as well as muscular coordination in the hands and other regions far removed from the site of the injury to the spine or the spinal cord.

SYPHILIS IN PREGNANCY

To the Editor—I am treating a woman, aged 21 for congenital syphilis. Her chief symptoms were keratitis and cornea. At the onset of treatment in January 1936 the blood Wassermann reaction was plus 4 and the spinal fluid Wassermann reaction was negative. She was given three courses of bismuth in oil 120 mg ten eight and six doses with two intervening courses of nearsphenamine (maximum dosage 0.45 Gm) continuously. The cornea disappeared completely. The keratitis resolved to a point at which objects can now be discerned. Three months intervened. The blood Wassermann reaction went down to plus 2 after six months of treatment but was 4 plus at the end of the course. It is now plus 4. I am planning six months of treatment this year with bismuth in oil and nearsphenamine as before but in smaller dosage. Will you please criticize the treatment? I shall welcome any suggestions for the future. I have advised her that it is safe to have a baby but to have treatment during pregnancy.

MD Pennsylvania

ANSWER—There is little criticism to offer of the treatment given thus far. The two courses of bismuth planned for the year should be augmented by two more courses of nearsphenamine followed by several courses of bismuth injections a year for two or three years to come.

The advice with regard to the question of pregnancy is open to criticism or at least to discussion. The possibility of the girl's having an infected child is small (especially if treatment is started early and continued throughout the pregnancy). The effect of the pregnancy on the keratitis presents a considerable hazard. In congenitally syphilitic girls in whom the interstitial keratitis appears late, as in this young woman, pregnancy will frequently precipitate an attack of interstitial keratitis or will cause a recurrence of a previous attack. In view of her age, 21, it would seem advisable, therefore, to postpone the possibility of her becoming pregnant for at least five years at the end of which time the advisability of her having a child should be reconsidered.

LOW BACK STRAIN

To the Editor—A white man aged 35 complains of pain in the lower part of the back which he dates to a time when he stooped down and arose suddenly about four years ago. The pain is most severe when he bends forward or lifts. His occupation compels him to be on his feet all day. He is well developed is about 5 feet 9 inches (175 cm) in height and weighs about 165 pounds (75 kg). His posture is good and no abnormal curvature of the spine is apparent. Examination revealed nothing significant except a slightly enlarged prostate. There is no tenderness over the site of pain. Cystoscopic examination gave negative results. The urine, the blood count and the blood chemistry were normal. A roentgenogram of the spine revealed a small fragment of bone posterior to the spine of the fourth lumbar vertebra, it is oval and about 0.5 cm in its longest diameter. There is also cloudiness between the last lumbar vertebra and the sacrum. The rest of the roentgenograms are normal. After several consultations the patient was given a choice between surgical intervention and diathermy with the wearing of a plaster jacket. One surgeon advocated the removal of the fragment of bone, one a fusion operation and another the plaster jacket and diathermy. What is the wisest step?

M D New York

ANSWER—Unless there is tenderness on palpation at the site of the small fragment posterior to the spine of the fourth lumbar vertebra, there would seem to be little indication for its removal. The history and the objective observations suggest strain of the lower part of the back. Injury to the intervertebral disk between the fifth lumbar vertebra and the sacrum with displacement of some of the disk substance backward into the spinal canal should be considered, but such an injury is most commonly associated with pain along the course of the sciatic nerve. It should be possible by manipulative tests to determine whether or not the pain in the back is related specifically to the sacroiliac joints or to the lower lumbar section of the spine. It seems most inadvisable to plan an operative fusion until more conservative measures have been given a thorough trial.

A plaster cast, which should be followed after six or eight weeks with a good brace, diathermy and corrective exercises such as have been described by Goldthwaite, Williams and others, may be expected to lead to restoration of normal function in a majority of such cases. Should this program fail fusion of the joints in question might be necessary, but only if it was reasonably certain which joints were causing the trouble.

MOSQUITO REPELLENTS

To the Editor—Is there anything more effective than oil of citronella for keeping mosquitoes away from the body? If not is there something to put in the oil to keep it from evaporating so quickly?

LEONARD T CARLSON M D Minneapolis

ANSWER—All repellents directed against mosquitoes have one common drawback the most efficient ones are highly volatile and their effect rapidly wears off. A successful repellent, besides being obnoxious to the mosquito, should have the following requirements: it should have a base that will retard rapid volatilization of the active principle, it should spread readily, and it should have such a consistency that it will adhere to the exposed body surfaces. Of the large number available the most satisfactory formula is probably oil of citronella 15 cc (one half ounce), spirit of camphor 7.5 cc (one-fourth ounce), cedar wood oil 7.5 cc and white petrolatum 60 Gm (2 ounces). The use of a phenol soap for washing may be of aid. For lawn parties or open air gatherings frequent undertable sprayings with Flit or any of the antimosquito sprays insures comfort for a considerable time.

BRASS PLUMBING

To the Editor—My dwelling is equipped with a water system in which the water for drinking purposes and cooking purposes is supplied through brass pipes. These pipes conduct both hot and cold water for all domestic and family purposes. The chemical composition of these brass pipes as accurately as I can ascertain is 67 per cent copper and 33 per cent iron. The household water supply that flows through these pipes is known to contain a small percentage of lime, probably coming from some normal deposits in the earth. The thing I wish to know is whether the brass pipes will have any injurious effect on the water, and thus an injurious effect on the health of my family during future years. The pipes were installed with the understanding that they were more durable and satisfactory than iron but there has been some question raised by neighbors as to their long time effect on the health of the family and I would like a medical opinion on that point.

M D Maryland

ANSWER—This query refers to brass pipes as being composed of copper and iron. Properly, brass is composed of copper and zinc, although this term is applied to a large number of alloyed metals even those containing as high as 50 per cent of lead with copper. In any event, any brass will contain some lead as an impurity, but probably plumbing brass will not contain a quantity of lead beyond 1 per cent. If this possible source of lead poisoning together with lead connections within buildings and lead soldering of brass pipes is eliminated appre-

hension need not be felt as to the toxic properties from such metals as copper, zinc or iron in plumbing. The daily intake of the average adult is perhaps as high as 4 mg of copper. This is derived from food, drinks and occasionally drugs. Some copper seems to be necessary in normal human economy. It is therefore conceivable that the small amount of copper derived from brass plumbing conduits may serve a beneficial effect. It has been observed that copper is serviceable in the treatment of certain types of anemia.

EXCESSIVE SALIVATION FROM DENTURES

To the Editor—A man aged 53 has been wearing false teeth (upper and lower plates) for fourteen months. He takes them out at night. He complains of an excessive amount of salivation. There is a formation ofropy thick mucoid saliva that is a constant bother to him. It is making him nervous and he desires relief. He has tried a refitting of plates with no relief. His dentist is an expert at least one of the best in the state. A good number of dentists physicians and nose and throat specialists have nothing to offer. His work prevents him from going without his teeth for a period. WILLIAM A FRITZ M D, Hickory N C

ANSWER—We have been unable to find any specific cure for this condition. It is apt to be caused from some kind of irritation such as dentures improperly fitted, or it could be allergic the denture material itself causing the irritation. Diet might also enter into this picture. We would suggest reducing carbohydrates, giving an abundance of fruit juices and increasing the liquid intake. Aside from this there seems to be little known about the condition.

ALLERGY IN DISTRICT OF COLUMBIA

To the Editor—A white man aged 31 had an allergic attack of one month's duration twice in January and from Thanksgiving to Christmas of 1936. The attacks can best be described as an angioneurotic edema of the face with multiple synovial effusions and urticaria. The lesions shift from one locality to another leaving no permanent sequela. There is no response to the administration of epinephrine ephedrine or calcium salts intravenously each attack apparently running a thirty day course and spontaneously clearing up on its own accord. Skin tests with forty of the commoner antigens revealed four reactions graded two or three plus but not sufficiently positive to be diagnostic. There is no possibility of these attacks arising from a thermic sensitivity or from a change of living conditions in the cold weather likewise all possible foci of infections have been eliminated. The patient has become despondent and thinks that he is doomed to undergo a thirty day attack every winter. Would I be justified in subjecting the patient to the gamut of two or three thousand skin tests in an effort to find a specific antigen? Is there any plant emanation in the District of Columbia which gives rise to allergic attacks in the winter? Could you advise me of any other procedure for diagnosis or treatment? Kindly omit name. M D District of Columbia

ANSWER—If the correspondent is correct in the assumption that the symptoms of the patient are of allergic origin, exciting causes both from within and from without need to be investigated. There are no plants in bloom in the District of Columbia during the winter months. However, contact with the leaves and stems of house plants should be kept in mind and "patch tests" performed with them. Similar tests should also be performed with all materials which the patient handles in the course of his occupation.

A list of the articles that enter into his diet should be carefully kept and should serve as a basis for a complete series of skin tests. The possibility of drug idiosyncrasy should not be overlooked.

The lack of response to epinephrine or ephedrine raises some doubt about the allergic character of the attacks. A blood smear should be studied, and the question of worm infestation demands consideration.

USE OF DIPHTHERIA ALUM TOXOID

To the Editor—In the directions accompanying a vial of diphtheria alum toxoid the makers caution against its use in children after the age of 8 years but do not give their reasons. Why is this warning given and what should be done when this toxoid is used in older children?

M D Iowa

ANSWER—Above the age of 8 and more particularly after 12, severe reactions sometimes occur when the customary dose of toxoid or alum precipitated toxoid is injected. These reactions may be both local and constitutional.

In susceptible persons beyond the age of 8 it is sometimes well to inject 0.1 cc of toxoid or alum precipitated toxoid intracutaneously before administering any of the immunizing agent subcutaneously. In fact, it has been claimed that 0.1 cc of alum precipitated toxoid when injected intracutaneously is equivalent in its efficiency to 1 cc. given subcutaneously. Intracutaneous injections are practically devoid of constitutional reactions.

In some contagious disease hospitals, doctors and nurses with positive Schick tests are always immunized with toxoid. No

consideration is given to the age factor and comparatively few severe reactions are observed. Some physicians still prefer to use toxin-antitoxin for the purpose of establishing active immunity to diphtheria in older persons.

IODIZED SALT IN BOARDING SCHOOL

To the Editor—Kindly advise me as to the desirability of the routine use of iodized salt in a girl's boarding school with an age range of from 12 to 18. The incidence of thyroid disease, chiefly adenoma, is relatively high here. I have been impressed with the reports of Marine and Kimball but am a little uncertain on account of adverse reports by Lahey and others.

ALEX F ROBERTSON JR M D Staunton Va

ANSWER—It certainly would be desirable to carry out some method of prophylaxis against goiter in a girl's boarding school with an age range of from 12 to 18. The routine use of iodized salt, preferably one of the nationally advertised brands, would probably be desirable. This method is adequate, easiest of all to carry out and teaches the fundamental principle that goiter is one of the deficiency diseases. Because of the adverse reports mentioned the state health department of Michigan has been making a careful study since 1928, and it has never found a case in which there was the slightest suggestion of injury to children of this age due to the use of iodized salt.

DRUGS USED TO SHORTEN MENOPAUSE

To the Editor—One of my patients tells me that several months ago a physician in another state told her about a new medicine that is used to shorten the menopause. She did not take the treatment at that time but now feels that she would like to take it. Is there a medicine on the market that is useful for the purpose mentioned or is it likely that she has in mind some remedy to relieve the symptoms of the menopause? If there is a remedy that will shorten the menopause where can it be obtained?

BIRON E CRAWFORD M D, Chamberlain S D

ANSWER—There is no medicine that will shorten the menopause, unless the patient interpreted radiotherapy to be a form of medication. Likewise as surmised, the patient may have been told only about medicines that will alleviate the disagreeable symptoms of the change of life.

INTRAMUSCULAR INJECTION IN BUTTOCKS

To the Editor—On page 1134 of THE JOURNAL March 27 under the heading Intramuscular Injection in the Buttocks the statement is made: Give the injection in the upper and outer quadrant always. This question had presented itself on several previous occasions therefore I consulted Dr M B Parounagian who in response to a letter of June 25 1936 replied: Upper and inner quadrant because the patient does not sit on that region less blood vessels and away from the sciatic nerve causing less pain. I have followed Dr Parounagian's suggestion in directions for use of injectable aqueous colloidal bismuth. However I would appreciate your comment as I wish to distribute authoritative information concerning such matters.

HARRY NOONAN Long Island City N Y

ANSWER—In getting ready for an intramuscular injection in the buttocks, it is well to divide the buttock into quadrants, an invisible line may be dropped down the center of the buttock and a line at right angles to this across the middle transversely. The injection should be given in the outer quadrant at the inner angle. In this area there is the least danger of affecting nerve structures or large vessels, and of causing a deposit that will be irritated when the patient sits down.

TYPHOID VACCINE THERAPY IN NEUROSYPHILIS

To the Editor—Please send me information regarding the method of carrying out the Nelson technic of typhoid vaccine therapy in treatment of neurosyphilis.

M D Wisconsin

ANSWER—Nelson's article appeared in the *American Journal of Syphilis* 15 185 (April) 1931. The method was devised to produce higher body temperatures without the use of unreasonably large doses of vaccine. A single intravenous dose of from 15 million to 250 million, depending on how many previous injections had been given, will produce a temperature of about 102.5 F. In order to produce the desired 105 to 106 F it was necessary to give as much as from 3,000 million to 4,000 million. Nelson found that if two successive doses are given on the same day the desired temperature may be reached. At the height of the temperature produced by the first dose, usually from two to three hours after the injection, a second injection is given with the resulting elevation of the temperature to 105-106 F. All injections are given intravenously. The first dose varies from 15 million to 250 million and the second dose varies from 20 million to 300 million, depending on how many hyperpyrexial attacks have been produced previously.

GROWTH OF FUNGI IN FOODS

To the Editor—How many days can prepared foods stand in ordinary temperatures and not become a medium for the growth of fungi? Are common refrigerators free from fungi and a safeguard to our food from such infestations? We would not eat bread and biscuits that had stood for weeks or months. In a lesser degree are not crackers and wafers that stand for days weeks and months in our groceries infected with fungi? Is it possible for a sclerosed gastro-intestinal tract with little digestive juices not to become infected and mycosed by these long standing unsealed prepared foods?

M D Indiana

ANSWER—There is no clear-cut evidence to indicate that molds which commonly produce spoilage in food are pathogenic to man. Air and soil contain many mold spores which germinate and grow when they have suitable food moisture, temperature and time. Common refrigerators are not free from fungi.

ALLERGY TO COOKED ONIONS

To the Editor—A patient reacts allergically about the eyes to cooked onions but not to raw onions. It is the only food to his knowledge to which he is sensitive. How prevalent are onions as an allergin and why doesn't he react to them raw?

W EDWARD MCGARVEY M D Jackson Mich

ANSWER—Ordinarily raw foods are more antigenic than cooked foods. Examples of the reverse have not come to our attention. It is possible, however, that if the exposure is due to the volatile material from the onions by way of the respiratory tract the procedure of cooking would throw into the atmosphere much more of that material. Asthma due to the vapors of cooking foods have been described (Feinberg, S M, and Aries, P L. Asthma From Food Odors, THE JOURNAL, June 25, 1932, p 2280). Onion is a fairly common allergen.

PLASTIC INDURATION OF PENIS

To the Editor—A man aged 50 has chronic circumscribed inflammation of the corpora cavernosa sometimes called circumscribed fibrosis. The patient noticed this mass developing in the penis six months ago. It is gradually extending toward his symphysis. At present it is about 2 cm long. He has attended numerous physicians for the condition with no results. I would appreciate information on this condition as to treatment and prognosis. Please omit name.

M D Florida

ANSWER—This condition is known as plastic induration of the penis. It is usually a progressive condition, although roentgen treatment has been known to control it in some cases. However, care must be taken not to include the testes in the exposure to x-rays.

PROTAMINE IN IMMUNIZATION

To the Editor—Since protamine slows down the absorption of insulin I wonder whether it would be possible to combine protamine with antigens in order to lessen the danger of anaphylaxis and to avoid other untoward reactions. I have especially in mind the scarlet fever immunizing treatments and antiallergic therapy in general.

R R GUTSTEIN M D Kendallville Ind

ANSWER—This is an interesting suggestion, but only by experiment would it be possible to find out whether the combinations suggested can be effected with practical advantage in immunization.

FATALITY AFTER INJECTION OF VARICOSE VEINS

To the Editor—In your reply to the query entitled Fatality Following Injection of Varicose Vein (THE JOURNAL May 22 p 1872) you state that allergic reactions following injections of sodium morrhuate are uncommon. In our experience at the V V department of the North End Clinic at Detroit these reactions are rather common. We have a series of about fifteen such rather serious reactions although luckily no fatalities. These cases are to be reported soon in the literature by Dr Saul Rosenzweig and myself. In order to obviate these reactions or at least minimize their severity we worked out the following method of procedure.

The first injection of sodium morrhuate is always less than 0.5 cc of 5 per cent sodium morrhuate. If the patient shows no allergic manifestations after the first injection the dose is increased. If the patient does not get any injections for a period of one month or more on subsequent treatments we proceed as if it were a new patient and with even more caution because the patient may have become sensitized by the previous injections plus the intervening rest period.

It appears to me that the dose of 2.5 cc of 5 per cent sodium morrhuate given to the patient in the cited query was entirely too large considering the previous injections and the intervening rest period.

In concluding I want to call your attention to the fact that there is a sclerosing solution which is entirely free from allergic reactions. This is a 20 or 30 per cent of sodium chloride. The disadvantages of this sclerosant are two severe cramp for a few minutes following the injection and the danger of slough if even a few drops of the solution are injected outside the vein.

Book Notices

The Diagnosis and Treatment of Diseases of the Liver and Biliary Tract By John Phillips Revised by Russell L. Haden M.D. Head of Department of Medicine The Cleveland Clinic Cleveland Ohio Henry A. Christian M.D. ScD LL.D. General Editor of the Series (Reprinted from Oxford Monographs on Diagnosis and Treatment) Cloth Price \$7.00 Pp 539 with 58 illustrations New York Oxford University Press 1936

This work, the manuscript of which was finished only a short time before the tragic death of Dr. Phillips, has been revised by his successor, Russell L. Haden. The book is divided into four parts. The first part begins with an interesting and adequate chapter on the embryology and anatomy of the liver, followed by an account of the physiology of the liver in which the essential features are presented succinctly and without unnecessary elaboration. The next chapter discusses the methods of examination of the liver and of the gallbladder, describing physical examination, examination by the x-rays and the chemical examination of the bile. The methods used in cholecystography are described in detail and the value and limitation of this new method of study are adequately considered. The first part closes with an excellent consideration of liver function tests. Here all the better known methods are discussed in detail and their technic and value considered. The second part of the book describes diseases of the liver. This section contains an excellent discussion of jaundice, cirrhosis, syphilis and certain other less common diseases. The bile ducts and their diseases occupy some forty pages, and this is an excellent section. The final section considers diseases of the gallbladder, with more than forty pages devoted to the discussion of gallstones. The book is readable, is well printed and contains a number of excellent illustrations. Each chapter is followed by a bibliography, which is both comprehensive and modern. The author, while obviously familiar with the literature on the physiology of the liver in its numerous aspects, has wisely restrained himself from discussing everything concerned with the various diseases portrayed. It is obvious to the reader that the author has had a wide experience in the treatment of diseases of the liver and also with the literature on the subject. All in all, the book is a clear and comprehensive discussion of the diseases of the liver and presents a satisfactory summary of the present state of our knowledge.

The Morphine Habit and Its Painless Treatment By G. Lughton Scott M.R.C.S. B.A. Second edition Cloth Price 5s Pp 105 London H. K. Lewis & Co. Ltd. 1937

The author has developed a method for the treatment of morphine and heroin addiction which in suitable cases, he believes, is so free from the distressing withdrawal symptoms that he speaks of it as 'the painless treatment'. He considers the word 'habit' misleading as applied to morphinism. 'A bad habit implies voluntary continuance in some asocial or antisocial practice, whereas the dependence of morphinism is as involuntary and relentless as thirst in the desert. It is unusual to meet the addict, however inveterate, whose dearest wish is not the desire to be cured.' In established addiction the stimulating effect of morphine is more pronounced than the narcotic. There is a 'kick' in each injection which rallies the addict's diminishing powers of mental application and enables him to work at increased pressure without fatigue. If the pulse is taken before and after a dose, its perceptible slowing and strengthening is invariable. The author considers this vagus stimulation, as evidenced by slowing of the pulse, as an important guide to the presence of tolerance. In a

normal person as minute a dose as 2 or 3 mg. produces a slowing of the pulse by several beats a minute, a feeling of euphoria and increased vigor. As tolerance develops, it takes progressively larger doses to produce this vagotonic effect. The author therefore regards the addict as one who has been accustomed to sustain an artificial vagal preponderance by means of this drug and that symptoms of too rapid withdrawal are due to diminution of the vagal control and to sympathetic overaction while sudden abstinence ushers in a "series of sympathetic explosions which may even endanger life." The author believes that during a gradual reduction treatment one can by the administration of atropine imitate the vagosympathetic relation which the morphine addict requires to be comfortable. The following simplified technic illustrates the principle of the method. Six-tenths mg. of atropine is dissolved in 48 cc. of physiologic solution of sodium chloride together with the full daily supply of the morphine. A dose of 4 cc. is injected every two hours while the patient is awake, but he is not to be aroused when he is asleep. Thus, the more he sleeps the fewer doses he needs and gets. The quantity of morphine actually consumed on the first day becomes the total amount introduced into the mixture for the second day, and so on, until the drug is entirely withdrawn. While the morphine is gradually cut down the atropine is gradually increased until as much as 0.3 mg. of atropine may be included in every dose. The aim is to maintain a slower than normal heart beat. The appearance of ocular symptoms is a sign that atropine is being increased too rapidly. Such a scheme is self-regulating and automatic allowance depends inversely on the length of time the patient sleeps. The author admits that this treatment is unsuited to the debilitated and that segregation, a tactful nurse and a consecrated physician are requisites for success. He reports about two dozen cases illustrative of his method, which is not as simple in its execution as the condensed presentation of principle might lead one to suppose.

Reading, Writing and Speech Problems in Children. A Presentation of Certain Types of Disorders in the Development of the Language Faculty By Samuel Torrey Orton M.D. Cloth Price \$9 Pp 115 with 24 illustrations New York W. W. Norton & Company Inc. 1937

This book contains the Thomas W. Salmon Memorial Lectures given at the Academy of Medicine in 1936 by Dr. Samuel Torrey Orton. In these lectures Dr. Orton presents the results of his research and studies in language disorders over a period of more than ten years. In the first chapter certain disturbances of language which follow injury to the brain in the adult are briefly reviewed and attention is called to the arresting fact that these disorders may follow a lesion in one hemisphere of the brain but only if it is the master half of the brain that is injured. The author further points out that our only guide to the master hemisphere in the adult is his laterality and observations in children are reported which indicate a wide range of variability in establishing a clear cut laterality as measured by tests and history of development of handedness, eyedness and footedness. 'In the second chapter five syndromes of delay or disorder in the acquisition of language were described—developmental alexia, special disability in writing, developmental word deafness, motor speech delay, and stuttering—and one other—developmental apraxia—which follows the same unilateral pattern of organization in the brain although it does not always interfere with language development. In all but one of these six disorders, viz., stuttering, it was pointed out that the symptoms observed are a very exact counterpart of those seen in the corresponding syndromes in the adults suggesting strongly that the determiner for these disabilities in childhood is very closely related physiologically to that which is disturbed by lesions in the critical cortices controlling language in the adult.'

The author finds one common factor in all the difficulties listed: that engrams (physiologic records of previous stimuli left in the brain or other nerve centers) exist in the nondominant hemisphere which, if not completely elided, may cause confusion in recognition and recall. There is a clear and suggestive discussion of the treatment of the language difficulties that are listed. Contrary to some of his followers, the author does not feel there is any one single method which can be used in each case nor does he believe that his methods can be standardized. He points out that the emotional factors in every case must be

carefully studied and personality disorders wherever found must be treated. He divides stutterers into two types—those who stutter from the time they first begin to talk and those whose speech is normal until the sixth to the eighth year. He says that in the younger group it is exceedingly important to determine whether a shift of handedness away from the natural inclination has taken place or is under way. Motor tests as well as careful inquiry into the history is essential here. It is well to emphasize the author's words about stuttering given in chapter 5. He says, with regard to the frequently heard statement that all stutterers should have been left-handed and ought to be so trained that this rests on a superficial comprehension of the complexities of the problem of cerebral dominance and of the potential sources of difficulty. It is frequently difficult to decide which hand should be used in writing. The book is clearly and interestingly written. The author is careful in drawing his conclusions and modest in his assumptions. It is unfortunate, however, that the book has no index.

This book is a milestone in the study of speech disorders, and no one who works in this field can afford to be without these stimulating and interesting lectures.

Laboratory Outline in Filterable Viruses. By Roscoe R. Hyde. Professor of Immunology and Director of the Laboratories of Immunology and Filterable Viruses, School of Hygiene and Public Health, The Johns Hopkins University. With the assistance of Raymond E. Gardner, Associate in Immunology. Cloth. Price \$1.50. Pp. 85 with 3 illustrations. New York: Macmillan Company, 1937.

In their small volume the authors have presented brief directions "planned to give the student a first-hand knowledge of the nature and behavior of a number of representative viruses" and "a more comprehensive experience with the pathology of a selected group of virus diseases ranging from necrosis to hyperplasia." The text has been evolved from laboratory notes used for a number of years in the teaching of courses at the School of Hygiene and Public Health at the Johns Hopkins University, where the late Charles E. Simon established the first university department of filtrable viruses in the United States. The exercises are designed as an introduction to the study of the filtrable viruses. In preparing them, the choice of viruses and methods has been governed by questions of suitability for class use. They are planned with the idea that the work can be completed within the time allocated for the laboratory period. The directions are stated briefly. It follows that the student will require frequent consultation with an instructor to supply technical details. To make intelligent use of the exercises, the student must have been well grounded in general science and must have received adequate training in bacteriology, immunology and pathology. Thus the volume will be most serviceable to the teacher confronted with the problem of giving a small number of well prepared students a practical introduction to the filtrable viruses. For the more advanced student and the research worker the volume will not be very helpful. A number of technical methods are described including filtration, the preparation and use of collodion membranes, electrophoresis, tissue culture and the making and staining of histologic preparations. The descriptions of these methods have been gathered from many sources for the convenience of the student. The viruses selected for study exemplify a number of types. They include the viruses of bacteriophage, tobacco mosaic, lymphocystic disease of fish, vaccinia and variola, fowlpox, herpes, rabies, Rous sarcoma, poliomyelitis and yellow fever. Selected references are given with a view to guiding the student to suitable reading material for use in connection with the laboratory work. This selection is rather arbitrary and inadequate.

Bolezni ukha, nosa i gorla. Rukovodstvo dlya vrachev. Pod redaktsiyey S. M. Kompaneysa i trekh tomakh Tom perry. Bolezni ukha. Pod redaktsiyey S. M. Kompaneysa i A. A. Skrypta. Chast pervaya. [Diseases of Ear, Nose and Throat. Handbook for Physicians. Volume I. Diseases of Ear. Part 1.] Cloth. Price 18 rubles. Pp. 638 with illustrations. Kiev: Gosudarstvennoye Meditsinskoye Izdatel'stvo, 1936.

This is the first half of volume I. It is intended as a guide for otorhinolaryngologists and not as a textbook for students. The contributions are from Soviet specialists. The volume contains an extensive contribution by A. M. Puchkovskiy dealing with the history of the development of otorhinolaryngology in former Russia and in the Union of Socialist Soviet Republics. This is followed by chapters on the anatomy, comparative

anatomy, histology, physiology and pathology of the ear, otoneurology, the technic of physiologic experiments on the ear, and on the methods of investigation of the organ of hearing. All the chapters are adequately treated. The illustrations, while lacking artistic appearance, are well selected and valuable when considered from the scientific point of view. Particularly valuable is the chapter on the relation of otology to neurology.

The Facial Neuralgias. By Wilfred Harris, M.D., F.R.C.P., Consulting Physician to St. Mary's Hospital, London. Cloth. Price \$2.75. Pp. 109 with 15 illustrations. New York & London: Oxford University Press, 1937.

This excellent treatise is another masterpiece by Wilfred Harris, the author who contributed the textbook of neuritis and neuralgia to the medical profession. The present work is a detailed compend attempting a classification and differential diagnosis of the many and baffling types of facial pain. Its contents include dental neuralgia, neuralgia from ocular causes, trigeminal tic, migrainous neuralgia, physiology of sensory conduction from the face, sympathetic sensory conduction, traumatic neuritis of the trigeminal and its branches, post herpetic trigeminal neuralgia, tumors of facial bones, nasopharynx or base of the skull, medullary sclerosis, geniculate neuralgia, facial psychalgia, headache and facial neuralgia in sinusitis, chronic neuralgia of the jaws, temple side of head and neck, and glossopharyngeal tic. The proved and the theoretical data are amply discussed. The author also has placed at the disposal of the readers his knowledge and experience gained in the treatment of trigeminal tic during the past twenty-eight years. There is an excellent bibliography. This book is the best treatise on facial neuralgias in medical literature today.

William Withering. The Introduction of Digitalis into Medical Practice. By Louis H. Roddis, M.D., Commander, Medical Corps, United States Navy. Reprinted with additions and corrections from *Annals of Medical History* (New Series, Vol. VIII, Nos. 2 and 3, March and May, 1936). Cloth. Price \$1.50. Pp. 131 with 8 illustrations. New York: Paul B. Hoeber, Inc., 1936.

This volume is uniform with some of the previously published monographs on great pathfinders in medical practice published by the Hoeber press. It is apparently the first formal biography in book form of William Withering, whose contribution to cardiology is everywhere recognized as epoch making. Withering was much interested in botany, mineralogy and other scientific subjects. He developed a considerable consultation practice. He first used foxglove in 1775. The manner in which it was first called to his attention is interesting. He says:

In the year 1775 my opinion was asked concerning a family recipe for the cure of dropsy. I was told that it had long been kept a secret by an old woman in Shropshire who had sometimes made cures after the more regular practitioners had failed. I was informed also that the effects produced were violent vomiting and purging for the diuretic effects seemed to have been overlooked. This medicine was composed of twenty or more different herbs, but it was not very difficult for one conversant in these subjects to perceive that the active herb could be no other than foxglove.

The book makes an interesting biographic story out of the life of a great physician. It is beautifully illustrated and has a fine bibliography.

Senile Cataract. Methods of Operating. By W. A. Fisher, M.D., F.A.C.S., Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College. Third edition. Fabrikoid. Price \$2. Pp. 153 with 183 illustrations. Chicago: H. G. Adair Printing Company, 1937.

Ophthalmoscopy, Retinoscopy and Refraction with New Chapter on Orthoptics. By W. A. Fisher, M.D., F.A.C.S., Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College. Fourth edition. Fabrikoid. Price \$2. Pp. 210 with 240 illustrations. Chicago: H. G. Adair Printing Company, 1937.

The book on cataract contains brief chapters by Fuchs (now dead), Wright, Barraquer, Holland and van Lint. On the whole the illustrations are poor except for the charming picture of two kittens, which furnish "ample, inexpensive and satisfactory material for practice." The appearance of the book is attractive. The material presented is too complex for the medical student insufficient for the beginning ophthalmologist, and inadequate for the experienced ophthalmic surgeon.

The second book has a new chapter on orthoptics but retains the same old Cleveland fundus plates which are perfectly unintelligible. Retinoscopy, refraction, ophthalmoscopy and orthoptics are discussed at wholly inadequate length.

Heart Disease By Paul Dudley White M.D. Lecturer in Medicine Harvard Medical School Second edition Cloth Price \$7.50 Pp 744 with 125 illustrations New York Macmillan Company 1937

The second edition of this deservedly popular book is a vast improvement over the first. The book has been entirely revised and many better illustrations have been provided. The extensive bibliography of the first edition has been abbreviated and brought down to date. Its utility has been greatly enhanced by placing the references at the end of each chapter instead of, as before, at the end of the book. Otherwise, the same plan has been employed as in the first edition, but the first section dealing with the cardiovascular examination has been considerably reduced. It is regrettable that in this reduction the chapter on symptoms seems to have been greatly shortened. The same saving in space could more suitably have been obtained if the chapter on auscultation had been reduced and some of the polygraph and apex beat tracings in the chapter on pulsations had been omitted. Considerable reduction in size could also have been obtained by reducing the repetitions, not all of which can be ascribed to the scheme of the presentation. It is unfortunate that the recent developments in the field of peripheral vascular disease were not given more consideration. The author has added two new appendices, the first is the classification of cardiac diagnoses approved by the American Heart Association with some of the author's criticisms, and the second is a chronological summary of the major contributions to our knowledge in the cardiovascular field. It would have been better if the last twenty-five years of this historical summary had been omitted from this survey, since it is obvious that historical judgment improves with lapse of time. These comments do not detract from the excellence of this book, which represents not only the personal experience of the author over many years in the practice of cardiology both among private and among service patients, but also the points of view that have developed in the field in the last quarter century. The medical student and general practitioner will find the book easy to digest and full of practical and useful data. The specialist will find a considered, mature assay of the developments in this field dealt with from the clinical view. This book will take its rightful place among the classics in the field of cardiology.

Operative Surgery By Alexander Miles M.D. LL.D. F.R.C.S. Consulting Surgeon Royal Infirmary Edinburgh and D.P.D. Wilkie M.D. F.R.C.S. Professor of Surgery University of Edinburgh Second edition Cloth Price 21s Pp 631 with 329 illustrations New York & London Oxford University Press 1936

In this edition the text has been completely revised, a number of old illustrations have been withdrawn and a greater number of new ones added. As the authors justly state, the scope of operative surgery has become so wide and the technic so complicated that it is impossible to deal with the whole subject adequately in a single volume of moderate proportions. The work is offered to undergraduates and resident surgeons as a description of the present-day practice in the Edinburgh school, the alternative methods have been discussed only in general outlines. From the purely theoretical point of view, it is beyond doubt that a medical student should be familiar with ligation of the common carotid or the iliac artery, however, when sixty-three pages is devoted to blood vessel surgery the question arises whether it is not wiser to allot less space to the description of such rare procedures and devote more to common operations. The compilative, concise yet comprehensive work is profusely illustrated for the Edinburgh student the book fulfils a distinct need for the American surgeon it will be of interest as it furnishes information as to methods popular in this prominent medical school.

Pediatric Nursing By John Zahorsky A.B. M.D. F.A.C.P. Professor of Pediatrics and Director of the Department of Pediatrics St. Louis University School of Medicine Assisted by Beryl E. Hamilton R.N. Graduate of St. Luke's Hospital St. Louis Cloth Price \$3 Pp 568 with 151 illustrations St. Louis C.V. Mosby Company 1936

Pediatrics has progressed as rapidly as any phase of medicine, consequently, pediatric nursing has also needed modification and study. The prevention of diseases has been increasingly emphasized, and proper nutrition to provide for normal growth has become one of the primary objects of child care. Almost daily, new technical procedures on the care of the sick infant are

presented. This book was written to supply the need for material describing the latest methods used in pediatric nursing. The first section of the book is devoted to the science of pediatrics, the second, to the technical methods of procedure. Profuse illustrations, although not always clear, may aid the nurse in understanding the methods described. While actual practice in a hospital is needed in the training of nurses, the use of a suitable textbook, such as this one, will aid greatly.

Atlas gisteroskopii v akusherstve [By] B. I. Litvak. Pod redaktsiev Prof. G. F. Plenskogo. Atlas de l'hystéroscope dans l'obstétrique. Cloth. Price 27 rubles 50 kopecks Pp 151 with 50 illustrations Kiev Gosmedizdat U.S.S.R. 1936

The author discusses the diagnostic value, the construction of the instrument and the technic of endoscopy of the uterus with the aid of the Miculicz-Radecki-Freund hysteroscope. The method enables the observer to recognize the various inflammatory and edematous states of the uterine mucosa, fetal remains and localization of the placenta. The author studied epithelization of the uterine cavity after artificial abortion and after normal labor. The results of the investigation are presented in fifty drawings. The author believes that endoscopy of the uterine cavity is a valuable aid in gynecologic and obstetric diagnosis and that it deserves further development.

The Nursery Years By Susan Isaacs M.A. D.Sc. Reprinted 1936 Cloth Price \$1.50 Pp 138 with one illustration New York Vanguard Press 1936

This guide book was originally published in April 1929. It describes the mental development of the infant until the age of 6 and includes chapters on the norms of development, some answers to problems, and playthings. On one page the author epitomizes fifteen important don'ts for parents. References are classified describing the general facts of development therapy and practice in education and biology. The language is simple and the material authoritative. This little volume lends itself well as an elementary textbook for child study groups and can be recommended for teachers and pediatricians interested in child development.

Textbook of Medicine By Various Authors Edited by J. J. Conybeare M.C. M.D. F.R.C.P. Physician to Guy's Hospital London Third edition Fabrikoid Price \$7 Pp 1027 with 49 illustrations Baillière Tindall & Co. 1936

The object of this book is to provide to the student and practitioner the essentials of medicine within as small a compass and at as low a price as possible. In the present edition the subject matter has been revised, in many places rewritten, and several additional contributors have been added. The sections on renal diseases, anemia, diabetes mellitus and the pituitary gland have been completely rewritten. A new article on coronary occlusion has been included. The material on arthritis has been rewritten to conform with the modern outlook toward this disease. Many prescriptions have been added which increase the value of the book for the practitioner. The author has accomplished in a large measure his purpose of including a large amount of material in a book of not excessive size.

Economic Problems of Modern Life By S. Howard Patterson A.M. Ph.D. Professor of Economics Wharton School of Finance and Commerce University of Pennsylvania and Karl W. H. Scholz A.M. Ph.D. Professor of Economics Wharton School of Finance and Commerce University of Pennsylvania Third edition Cloth Price \$4 Pp 813 with 35 illustrations New York & London McGraw-Hill Book Company Inc. 1937

The previous editions of this work were published in 1927 and in 1931. It is a first class textbook on economics, concerning itself with the organization of business exchange, public and private finance, capitalistic organization, labor problems and security. The final section is devoted to world problems of economic reorganization. The whole subject of public health is discussed under the heading of "Economic Insecurity and Social Insurance." Here the authors advocate some sort of sickness insurance for all workers.

Naris klinichnoi fermentologii [By] I. V. Bazilevich [Outline of Clinical Fermentology] Paper Price 9 rubles 6 kopecks Pp 314 Kiev Vidavnistvo Akademii Nauk U.S.S.R. 1936

This book, written in the Ukrainian, deals with the various ferments of the human body, the various tests for their recognition, their chemistry and their clinical significance.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Liability of Physician for Negligence of Hospital Nurse—The plaintiff was suffering from a small dermoid cyst in the pelvic region and entered the Church of St. Matthew Mills Memorial Hospital to have it removed by a Dr. Prindle. The physician requested a nurse in charge of the operating room to prepare for a minor operation, informing her that he would use as a local anesthetic a 1 per cent solution of procaine. Through mistake, the nurse prepared a solution of formaldehyde which the physician, believing it to be procaine, started to inject into the plaintiff in the immediate vicinity of the cyst. The patient immediately gave evidence of suffering great pain and the physician, discovering the mistake, injected procaine and completed the operation by removing the cyst after excising the area affected by the formaldehyde. Thereafter the plaintiff sued the physician, the hospital and the nurse. In the first trial of the case, the trial court gave judgment for the defendants but the Supreme Court of California remanded the case for a retrial. *Hallman v Prindle* (Calif.), 29 P. (2d) 202, abstr. THE JOURNAL, Oct. 13, 1934, p. 1178. In the second trial the trial court gave judgment against the hospital and the nurse for the sum of \$12,500 and exonerated the physician from liability. The hospital, the nurse and the plaintiff appealed to the district court of appeal, first district, division 1, California.

The court could find nothing in the evidence to support the plaintiff's contention that the nurse, in preparing the tray for the operation, was the servant or employee or even the agent of the physician. While, said the court, if the physician were performing such an operation at the home of the patient, or in his office, without assistance, these preparations would necessarily devolve on him, there is nothing in their nature which renders it improper or even undesirable that they be undertaken by another person, qualified by training and experience, acting in cooperation with the physician. The nurse in performing her duties in the operating room is acting for her employer, the hospital, and not for the operating surgeon, and the latter cannot be held responsible for her negligent acts unless performed under conditions in which, in the exercise of ordinary care, he could have or should have been able to prevent their injurious effects and did not. The general rule is thus laid down in 48 Corpus Juris, sec. 144, p. 1137: "A physician is not liable for the negligence of hospital or other nurses, attendants or internes who are not his employees if he has no knowledge thereof, or has no connection therewith, or if it is not discoverable by him in the exercise of ordinary care, or unless he is negligent in permitting them to attend the patient." It was plain from the evidence, the court continued, that the acts of preparation performed by the nurse were not done under the special supervision and control of the physician. On the contrary, they were performed by her in his absence. That they were done at his request or direction has no significance, since she was merely attending to duties devolving on her as an employee of the hospital. Whether performed by her at the direction of an officer of the hospital made in pursuance of a previous notification by the physician or on the request of the physician made directly to her cannot affect the legal situation.

The trial court committed no error in admitting evidence of the custom of physicians and surgeons of good standing to accept instruments, medicines and drugs from a graduate trained nurse without making an examination thereof themselves. The jury was called on to decide whether the physician was chargeable with negligence in injecting into the body of the patient the liquid placed by the nurse in the medicine glass. The test of such negligence is whether or not an ordinarily prudent person would have acted as the physician did. Although jurors are presumed to know what an ordinarily prudent person would do under any and all circumstances, it is of assistance to them to be informed what the practice is of persons habitually called on to perform a given act, for it is obvious that such a practice is most likely to be that which

is suggested by ordinary prudence. While a negligent act, clearly shown to be such, cannot be justified on the ground of custom or usage, and evidence of such custom or usage is not generally admissible for that purpose, evidence that a person charged with negligence followed the custom of other persons in the same line of business will be received on the question as to whether he acted as a reasonably prudent man would have acted under the circumstances. The trial court committed no error in exonerating the physician.

With respect to the hospital, the court said, the evidence was clear that it was a nonprofit organization devoted to the care of the sick either without payment or at a charge which was less than the cost of such care. The hospital, being a charitable institution, was not liable for the negligence of the nurse, no lack of care having been shown in her selection and retention. The trial court erred, in the opinion of the district court of appeal, in allowing the verdict against the hospital to stand. With respect to the nurse, the court said, it could hardly be contended that she was not guilty of negligence. On the former appeal in this case, the Supreme Court held that the evidence conclusively established such negligence. The nurse accounted for her mistake by frankly admitting that she took no pains to read the label on the formaldehyde bottle before pouring part of its contents into the medicine glass. The court thought, however, that the amount of the judgment against the nurse was excessive by \$5,000.

For the reasons stated, the judgment in favor of the physician was affirmed, the judgment against the hospital was reversed and the judgment against the nurse was affirmed, subject to a reduction of \$5,000 if agreed to by the plaintiff. — *Hallman v Prindle* (Calif.), 62 P. (2d) 1075.

Medical Practice Acts Defective Charges in Revocation Proceedings—The Florida state board of medical examiners instituted proceedings to revoke Sbordy's license to practice medicine, charging that he "was guilty of fraud in the practice of medicine, or fraud or deceit in his admission to the practice of medicine." To substantiate this charge it was alleged that (1) he held a certificate of the board of eclectic medical examiners, dated April 6, 1915, "which said certificate is fraudulent and improper which fact is and has been well known" to him, and (2) he was not "a graduate of a legally incorporated medical college maintaining a standard satisfactory to the State Board of Medical Examiners of Florida." Prior to a hearing, Sbordy applied to the Supreme Court of Florida for a writ of prohibition to prevent the board from proceeding further.

The board questioned whether or not the desired remedy by prohibition was proper. The Supreme Court held that it was proper if the board was acting without jurisdiction or if it was exceeding its jurisdiction in not proceeding in accordance with the essential requirements of law. The court concluded that the board was exceeding its jurisdiction because the complaint on which the revocation proceedings were based did not sufficiently charge Sbordy with the commission of any act which constituted a ground for the revocation of his license to practice medicine. Charges before licensing boards, said the Supreme Court, need not be stated with the technical nicety or formal exactness required of pleadings in the courts yet the accused must be informed with reasonable certainty of the nature of the accusation against him and must be given reasonable opportunity to defend against the attempted proof of such charges. Proceedings in matters of this kind are summary in their nature but are not arbitrary or despotic, and the charges preferred must be specific.

The first charge, which accused Sbordy of being guilty of fraud in the practice of medicine, or fraud or deceit in his admission to the practice of medicine, because he held a certificate "which said certificate is fraudulent and improper which fact is and has been well known" to him, obviously failed to charge him in such fashion as to inform him, with reasonable certainty, of the nature and cause of the accusation against him. In what manner he had been guilty of fraud and why it was that the certificate granted him was fraudulent and improper did not appear from this charge. It failed to accuse him of being guilty of any acts which constituted grounds for the revocation of his license. The second charge against Sbordy failed also to state with reasonable certainty wherein

he was guilty of any fraud in his admission to practice, except that he was charged with not being a graduate of a legally incorporated medical college maintaining a standard satisfactory to the state board of medical examiners. But, said the court, the provisions of the act under which he obtained his license to practice as an eclectic required him to have only a certificate of graduation showing that he had taken not less than a two years course from some college of the eclectic school of medicine. The second charge, therefore, failed legally to charge the commission of any acts which constituted grounds for the revocation of Sbordy's license.

A permanent writ of prohibition was issued restraining the board of medical examiners from proceeding with the revocation matter—*State ex rel Sbordy v Rowlett (Fla)*, 170 So 311

Optometry Practice Acts Corporate Practice of Optometry in Missouri—A corporation operated a number of department stores in Missouri and leased to an optical company space for operation of optical departments in such stores. The company agreed to place graduate optometrists in charge of such optical departments, who were to be subject to all the rules and regulations of the corporation. Receipts from the operation of such optical departments were payable to the corporation, which after deducting 25 per cent of such receipts returned them to the optical company. The optical company furnished all the equipment, supplies and merchandise necessary for the conduct of the optical business, but all the advertising of such departments was in the name of the corporation. The attorney general of Missouri brought quo warranto proceedings, alleging that the corporation and the company were engaged in the practice of optometry without a license. The Supreme Court of Missouri, however, held that the defendants were not engaged unlawfully in the practice of optometry within the meaning of the optometry practice act and dismissed the proceedings—*State ex inf McKittick v Gate City Optical Co (Mo)*, 97 S W (2d) 89

Malpractice Inflammation of Bone Following Fracture—On February 11 the plaintiff, a young woman, suffered a comminuted fracture of the tibia of her right leg about 5 inches below the knee joint. She was taken to a clinic operated by the defendants, where, after roentgenograms of the injured leg had been studied, the fracture was reduced and a plaster-of-paris cast applied extending from above the knee to below the ankle. During the next fifteen days the plaintiff complained of pain in her leg and on several occasions the defendants opened the cast to relieve the pressure. Another roentgenogram, taken February 26, disclosed a slight overlapping of the bone. The plaintiff was hospitalized and a so-called "Brown splint" was applied. On March 16 the bones were found to be in apposition and another plaster-of-paris cast was put on the injured leg. The plaintiff continued to complain of pain in her leg and the defendants advised her to have diathermy treatments, which she did. Finally, the plaintiff consulted another physician, who took another roentgenogram. From this and her history of the case, he "inferred" that the pain with which she was suffering probably involved some inflammatory bone process and suggested that she consult a specialist in that field. This she did and a biopsy indicated that there was a chronic inflammation of the bone. No infection was found. Thereafter the plaintiff sued the defendants, claiming that they negligently failed to discover that she, while under their care, was suffering from inflammation of the bone. In the trial court the jury rendered a verdict for the plaintiff, and the defendants appealed to the Supreme Court of Minnesota.

The specialist testified that the inflammatory process in and about the injured bone was not caused by anything done or omitted to be done by the defendants. From his examination of the plaintiff and her history, he concluded that the case had been a complicated one, largely because of the fact that the plaintiff, in childhood, had infantile paralysis, which left her right leg somewhat crippled. The record, said the Supreme Court, was barren of expert testimony placing any blame on the defendants. Neither of the plaintiff's expert witnesses ventured any opinion as to when the inflammation, other than such as naturally and necessarily resulted from the fracture, commenced or as to what caused it. Obviously, the court said, this was a case wherein the testimony of competent medical

experts was necessary to establish liability. There must be proof of causal connection between the wrong complained of and the resulting injury. The burden of proving such negligent conduct rested on the plaintiff, and she failed to meet this burden. The trial court was directed, therefore, to enter judgment for the defendants notwithstanding the verdict—*Williamson v Andrews (Minn)*, 270 N W 6

Health Insurance "Permanent and Total Disability" Construed—The insured under a policy of health insurance brought suit against the defendant insurance company to recover certain benefits which the company promised to pay if the insured became permanently and totally disabled. From a judgment in favor of the insured, the insurance company appealed to the Court of Appeals of Kentucky.

The Court of Appeals was unable to agree with the insurance company's contention that the evidence relative to total and permanent disability had not warranted the submission of the case to the jury. The mere fact that the insured had occasionally done light work about his farm, had looked after his saw mill and had worked five days through a series of years in laying a pipe line was not conclusive on the question of permanent and total disability. The court pointed out that two physicians testified that he had tuberculosis and was unable to work, as manual work of any kind would be dangerous to his health and life. It was shown by the evidence that when ever he did work he expectorated blood and was confined to bed thereafter. Even the medical witness for the insurance company, continued the court, went no further than to state that the insured could do only light work. The court therefore held that it was proper for the lower court to submit the question of permanent and total disability to the jury.

The Court of Appeals, however, reversed the judgment in favor of the insured and remanded the case for a new trial because among other things the lower court in instructing the jury had submitted only the question of total disability and had neglected to charge that in order for the insured to recover he must also prove permanent disability—*Prudential Ins Co of America v Johnson (Ky)*, 97 S W (2d) 793

Compensation of Physicians Liability of Father for Services Rendered to Minor Child—The defendant's minor son fractured his arm in a high school basketball game and was sent by the coach to the physician plaintiff for medical attention. On the father's refusal to pay for the services rendered, the physician sued. From a judgment in favor of the physician, the defendant appealed to the court of appeals of Alabama.

A father, said the court of appeals, is under obligation, natural, moral and legal, to furnish necessities for his infant child. The term "necessaries," in this connection, contemplates and includes many things, and what are necessities is a mixed question of fact and law to be determined by the jury on the particular facts of each case. The court concluded that medical care is and always has been included among necessities and, when needed, medical care is a proper subject of recovery in a civil action. Accordingly, the court of appeals affirmed the judgment in favor of the physician—*Osborn v Weatherford (Ala)*, 170 So 95

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

The Astrocytomas—Alpers and Rowe analyzed a large group of astrocytomas in an effort to classify them histologically and to correlate their histologic with their clinical features. The division of the astrocytomas into fibrillary (solid and cystic) giant cell and cellular groups indicates the great preponderance of the fibrillary group and makes possible in the majority of instances a safe prediction of the course which the tumor will take. In general tumors of the fibrillary and cystic groups grow slowly and have correspondingly slow clinical courses. The piloid group of fibrillary astrocytomas, while very benign histologically, seems to be less benign in clinical features. Tumors of the giant cell and cellular groups grow more rapidly and correspondingly follow a more rapid clinical course than the fibrillary astrocytomas. Most of the fibrillary astrocytomas are represented by the diffuse, interlacing neuroglial carpet, which simulates the neuroglial arrangement in the normal white matter. The reason for the difference in appearance of these slowly growing tumors must remain at present a matter of speculation. Granting that the preponderance of fibrils in fibrillary astrocytomas is due entirely to their formation by the cells, it is still not evident what the stimulus is for their heavy deposit in some tumors as compared with others, or why some fibrillary astrocytomas develop as diffuse types and others as piloid types all of them being the result presumably of the same cell, the fibrillary astrocyte. In all the fibrillary tumors it is possible to find protoplasmic types of astrocytes as well as immature forms. The cellular form of astrocytoma is in reality the protoplasmic type but even in these tumors there is some fibrillar formation. Since it is not clear whether the lack of fibrils is due to the presence of protoplasmic astrocytes or to immature cells, it is deemed best to refer to these tumors as cellular astrocytomas. Similarly there is little doubt that the giant cell astrocytomas constitute a group in themselves. In appearance and structure they are quite different from the other groups.

Transmissible Leukemia in Mice with Atypical Cells—Barnes and Furth describe a transmissible strain of leukemia in mice, the malignant cells of which are not typically lymphoid,

myeloid or monocytic in type. The cells are not phagocytic but form giant cells similar to megakaryocytes and the giant cells of Hodgkin's disease. Transmission of leukemia is accomplished with material containing living cells but fails with cell-free material. The length of life after inoculation is in inverse relation to the number of leukemic cells injected. The disease is readily transmitted to mice of the stock in which this leukemia originated. Unrelated mice may be rendered susceptible to this disease by massive repeated doses of X-rays, but not by a single irradiation. Leukemic tumor tissue slowly frozen to -70°C transmits the disease, while that rapidly frozen to -30°C is entirely inactive. Slowly frozen leukemic tissue kept at -70°C during thirty-two days produces the disease as readily as that kept at this temperature for thirty minutes. These studies indicate that successful inoculations with frozen material are due to a few cells that have escaped destruction.

Fibrosis of Bone Marrow Associated with Leukemoid Blood Picture—Mettler and Rusk cite two cases presenting leukemoid blood pictures and fibrosis of the bone marrow. The clinical observations in the two cases reported are similar only in the qualitative aspects of the so-called leukemoid blood pictures. The illness of the first patient was characterized by a hemorrhagic tendency, thrombocytopenia and severe anemia. Enlargement of the spleen occurred late in the course of illness. At the outset a leukopenia occurred and immature forms of leukocytes were found in the blood smear. Prior to death a leukocytosis developed and concomitantly there was a definite increase in the number of immature leukocytes. The second patient showed the classic signs of myelogenous leukemia when first seeking medical aid. There was splenomegaly and leukocytosis, and myelocytes were present in the blood film. As the course of illness approached termination myeloblasts appeared in the blood and the patient developed in addition a severe anemia. On postmortem examination the two cases presented a striking similarity in the structural changes of the long bones. The medullary cavities showed increased fibrosis and a few spicules of cancellous bone which partially obliterated the hematopoietic tissue. A careful study of the sinusoids of the liver and spleen in the two cases failed to reveal any erythrogenic foci. In the first case the blood picture was compatible with a diagnosis of aleukemic myelosis whereas in the second case the changes were those typical of myeloid leukemia.

Aortic Commissural Lesion in Rheumatic Fever—Gross and Silverman base their discussion on a study of seventy rheumatic hearts, together with fifty normal hearts. The rheumatic material was segregated into six groups representing the various clinical courses that the rheumatic process may take. A number of inflammatory changes are found in the aortic root, wedge annulus ring subaortic angle and pericardial mantle which are characteristic of rheumatic fever and, to some extent, reflect the clinical course of the disease. Even when healing takes place the histologic characteristics of the

commissural lesion afford additional stigmas, which are of value in discerning a past rheumatic process. From a discussion of the pathogenesis of this lesion it appears that, even though the original infection may reach the aortic ring through several routes, in most instances the inflammatory granulation tissue passes from the pericardial mantle through the aortic root, wedge and annulus to reach the aortic rings. The latter show a much more flagrant inflammatory process, which spreads into the valve leaflets and, probably with the additional factor of trauma caused by the systolic and diastolic movements of the cusps, eventually leads to their agglutination.

Control of Yaws—Saunders points out that in Jamaica, British West Indies, an effort has been made to reduce the prevalence of yaws in an endemic zone by an intensive treatment method whereby a field unit attempts to locate all infectious or potentially infectious cases and treat them at regular intervals to render them noninfectious. This was accomplished between April 1933 and September 1934 in a territory (under control for three years) 7 by 15 miles in extent comprising nine adjacent areas with a total population of nearly 22,000. To satisfy the requirements necessary for yaws control, a semi-mobile field unit was organized. This consisted of a medical officer, a clerk, a dispenser and four sanitary inspectors. The program entailed survey and treatment in successively adjacent areas, with follow-up work spaced at more or less regular intervals. When a survey was completed in an area, a temporary clinic was established near the center of the territory. The two inspectors of the treatment team notified all persons who had been found to have lesions of yaws and all who had given a history of the disease within the past five years to report for examination and possible treatment. They checked up on all delinquents and kept the entire area under surveillance for new infections and for relapsing lesions among persons with the disease in latent form. In order to determine the relative effectiveness of nearsphenamine and bismuth salicylate in the control of yaws, the patients in each area were treated almost entirely with one or the other drug. Preliminary studies showed that six weekly injections of either preparation were sufficient to cause prompt healing of lesions in nearly all cases and to prevent relapses for a period of at least a year in 90 per cent of yaws patients treated with nearsphenamine and in 70 per cent of those treated with bismuth salicylate, the individual dosage being graded according to body weight. After the original treatment period, each area was visited again for a rapid resurvey at intervals of from four to eight months. An inspector was sent into the district about a month ahead of the treatment team to record the condition of all former patients and to arrange for their attendance at the clinic soon to be reopened. The inspector also visited all homes, searching for persons with new and relapsing yaws lesions, paying particular attention to persons exposed to infected individuals. Both the attack rate and the number of persons with yaws lesions were substantially reduced.

Greater success was gained in areas in which patients were treated with nearsphenamine, but satisfactory results followed the use of bismuth salicylate.

Chagas' Disease and the Complement Fixation Test.—Johnson and Kelser proposed to determine the degree of infection by *Trypanosoma cruzi* in a representative group of the population and to study further the reliability and usefulness of the complement fixation test. Out of 1,251 serums collected thus far from various places in Panama, thirty seven were positive to the test and eleven gave suggestive reactions, a combined rate of 3.83 per cent. The infection rate as determined by the test is low for children less than 15 years of age but rises sharply above this age. This may possibly be explained on the basis of a relatively high mortality from the disease in children. This possibility is strengthened by the few clinical observations that have been made in Panama. The complement fixation test is of distinct value not only in identifying active cases of Chagas' disease but in revealing the incidence of the infection, past and present. The survey indicates that the disease and human carriers of the organisms are more common than has been supposed.

Treatment of Dendritic Keratitis with Quinine Bisulfate—In the last two years, Selinger treated eleven adults having moderately severe to severe dendritic keratitis with quinine bisulfate in addition to the usual treatment with compresses, atropine and bandages. An ophthalmic ointment containing 2 per cent quinine bisulfate was applied to the unanesthetized conjunctival sac twice a day by the patient. No massage was used. The subjective symptoms improved from the beginning and in most of the cases the corneal lesion healed within a week to ten days. In practically all the cases the eyeball was pale within one or two weeks. In no case did the disease last more than three weeks. Recurrences have not

been seen to date. Most of the patients had an accompanying or preceding infection of the upper respiratory tract. The good results obtained with local quinine therapy suggest a destructive action on the virus producing the disease. The same treatment was also tried in a case of herpes zoster with corneal involvement. The result was good, the corneal lesion going on to healing within three weeks.

Acute Phlegmonous Enteritis—Clark and Wright cite two cases of acute phlegmonous inflammation seen at necropsy at the Bellevue Hospital. In one the condition was limited to the jejunum and in the other to the ileum. The pathologic and clinical characteristics in forty-one similar case reports gathered from the literature are reviewed. It appears that acute phlegmonous enteritis is a well defined clinical and pathologic entity, and although it is most likely an infection of the wall of the intestine with pyogenic micro-organisms of enterogenous origin, a port of entry is only rarely demonstrated. The possible relationship of the acute phlegmonous lesion of the intestine to chronic nonspecific inflammatory lesions of the intestine is discussed, and a case is presented which suggests a transitional stage between the two.

Painful Coccyx—Duncan states that from 1924 to 1934 278 (97 per cent were women) patients were admitted to the outpatient department of the New York Orthopaedic Dispensary and Hospital with the complaint of pain in the coccyx. The average age was 34 years. The most common cause of the fall in this group of patients was slipping on an icy pavement and landing in the sitting position. The interval between the time of injury and the time of the patient's admission to the hospital for treatment varied from three days to six months. Nonoperative treatment consisted of improving the patient's posture, having her sit erect and pull the buttocks in under the trunk, thereby taking the superincumbent body weight off the coccyx and causing the soft parts surrounding the coccyx to act as a natural cushion. Hot sitz baths for from twenty to thirty minutes twice each day proved of value. Constipation, when present, was relieved by suitable laxatives. Local massage has proved beneficial to many of these patients. Steady but firm stretching of the coccyx posteriorly has been done on patients for several consecutive visits, with relief from pain. This is done to overcome the spasticity of the muscles having their insertion on the coccyx and to prevent the formation of adhesions and contractures in the sacrococcygeal joint and the surrounding coccygeal structures. Local injections of from 70 to 80 per cent alcohol, physiologic solution of sodium chloride or 2 per cent solution of procaine hydrochloride have given only transient relief or were entirely unsatisfactory. Of the 248 patients treated by nonoperative methods, fifty-four were examined from one to four years after the onset of their coccygeal pain. Only two continued to complain of a painful or tender coccyx. Fusion of the sacrococcygeal and intercoccygeal joints had taken place in a large number of the patients, and in the remainder there was limited motion. This limitation of motion in the coccygeal joints, coeval with cessation of pain, is additional evidence that the coccygeal pain was coming from a lesion of the joint.

Injection of alcohol about the coccyx may not cause degeneration of the coccygeal nerves, but by causing scar tissue to form it may so limit motion of the coccyx that the pain is diminished or cured. In the two patients who continued to complain of coccygeal pain, motion at the sacrococcygeal joint caused an identical pain. Relief from pain was experienced within one month after the injury by thirty-six of the fifty-four patients, by eleven within two months and by five within six months. The results seem to indicate that the nonoperative form of treatment should be tried for a period of six months before operative resection of the coccyx is resorted to.

Thirty of the patients in the total group had operative resection of the coccyx. The average duration of their symptoms before resection of the coccyx was eighteen months. Patients were followed on an average for two years after coccygectomy. Twenty-two of these patients were relieved completely of coccygeal pain, three had only partial relief from pain and five were unimproved.

Control of Diabetes Mellitus with Protamine Zinc Insulin in Surgery—To evaluate the action of protamine zinc insulin with respect to control of the diabetes immediately after operation, Fowler and his colleagues selected a variety of cases with regard to type of anesthetic, type of operation and severity of the diabetes. The twenty-five cases included gangrene of the extremities cellulitis of the feet and carbuncle and other not minor conditions. The operations that were necessary in these cases included cholecystectomies, hysterect-

tomy, amputations, incision of abscess, repair of birth trauma and tonsillectomies. The average control of diabetes in comparable patients both before and after the operations was much better with protamine zinc insulin than with unmodified insulin. Though the action of protamine zinc insulin on the blood sugar is ordinarily slower than that of the unmodified insulin, by the use of large injections it may be made to act as rapidly as the unmodified product. Therefore, with respect to rapid action alone protamine zinc insulin is not contraindicated in preparation of diabetic subjects for operation or for control of postoperative emergencies. By proper dosage the action of protamine zinc insulin may be prolonged sufficiently by single daily injections to permit the use of intravenous injection of dextrose after operations and also the normal rate of healing of wounds. The sustained action also appears to be sufficient to permit healing of infected tissues (cellulitis).

Experimental Gas Embolism—Richardson and his associates investigated the problem of experimental gas embolism on dogs and consider the relationship between the rate of injection of air and the time necessary to produce death when air is administered intravenously. Following the intravenous administration of air, the animal either dies or recovers. When the amount of air injected is small the animal usually shows no signs of respiratory or cardiac distress. When larger amounts are injected, either slowly or rapidly, respiratory distress and cardiac embarrassment are evident, but the animal may survive and recovery be complete. On the other hand the dyspnea and cardiac embarrassment may be of such magnitude that the injection proves fatal. This fatal issue may be either immediate or delayed. When the injection of air is rapid, respiratory failure predominates and death occurs almost immediately, if sufficiently large amounts are given, instantaneously acute cardiac dilatation occurs and death is extremely rapid. When the air is injected at an intermediate rate or when a moderate amount of air is injected suddenly, respiratory and cardiac symptoms are evident. Although partial recovery takes place, the animal may develop acute pulmonary edema and die within a few hours. A bronchopneumonia may become superimposed on an otherwise nonfatal pulmonary edema, resulting in death after several days. Some anesthetized animals, following the injection of air tend to hyperventilate themselves very markedly. These animals can tolerate larger quantities of air than other anesthetized animals whose respirations are less markedly affected. The general condition of the animal, as evidenced by its systemic blood pressure, plays a great part in its tolerance to intravenously injected air. Much less air is fatal to an animal with a low blood pressure than if the blood pressure is normal. This is of paramount importance in considering the amounts of air that apparently may prove fatal in cases of criminal abortion with which there is associated trauma, pain, apprehension and loss of blood.

Alum-Ragweed Precipitate—Zoss and his co-workers isolated the precipitate produced by the addition of potassium alum to aqueous ragweed extract. They experimented with the substance on twelve guinea-pigs that were injected subcutaneously with 1 cc each of the suspension of alum ragweed precipitate (12,000 protein nitrogen units per cubic centimeter). An interval of twenty-two days followed. Three guinea-pigs

were injected intravenously with 0.25 cc of aqueous ragweed extract. These developed signs of definite anaphylactic shock but recovered. Each of the remaining nine guinea pigs received intravenously between 0.5 and 1 cc of the same aqueous ragweed extract. These died of typical anaphylactic shock. Intracutaneous injections of the undiluted suspension of alum-ragweed precipitate in amounts up to 0.2 cc in a series of normal subjects produced no local urticarial, erythematous or pruritic response. No determinable reactions were noted in normal subjects on subcutaneous injection of the undiluted suspension in amounts up to 0.5 cc. In the preseasonal treatment of twenty-four ragweed sensitive patients with alum-ragweed precipitate by the routine method of preseasonal pollen therapy, beginning with 1, 10 or more units (as was indicated by the sensitivity of the individual patient), the material was administered to the various patients in increasing amounts at intervals of from four to seven days. Different maximal doses were given to the various patients, the maximum varying between 200 and 5,000 protein nitrogen units. Good results were obtained in 42 per cent, fair results in 21 per cent and poor results in 37 per cent. A series of fifty control patients treated preseasonally in 1936 with aqueous ragweed extract in maximal tolerance doses showed 60 per cent good, 18 per cent fair and 22 per cent poor results. Patients who received the higher maximal doses of the precipitate had better results than those on lower maximal doses.

The Heart and Bronchial Asthma—Colton and Ziskin made a study of the heart in eighty-four cases of bronchial asthma. There were nine deaths in this group and six cases came to necropsy. From a pathologic standpoint the heart was not greatly involved in uncomplicated cases of bronchial asthma. Dilatation of the right side of the heart was found in one patient dying of acute asphyxia. Two cases complicated by various degrees of emphysema, bronchiectasis and lung abscess showed hypertrophy, dilatation and congestive heart failure. Pathologic changes in the six cases examined post mortem are reported. No clinical evidence of heart disease was found in the majority of cases. Definite evidence of right ventricular strain with a tendency to myocardial involvement was noted in the electrocardiographic study. It must be concluded that the heart does not remain singularly free from injury in bronchial asthma and that right ventricular strain with a tendency to myocardial involvement and heart muscle damage does occur as the disease progresses and emphysema ensues.

Fulminant Streptococcal Sepsis in Infancy—Rector encountered eight cases of a particularly lethal type of fulminating streptococcal infection in infants. The instances of acute sepsis described differ primarily because death follows the onset of a bacteremia so quickly that localizing signs referable to individual organs rarely have time to appear. The disease is not primarily a pneumonic process but rather a widespread involvement of the entire body secondary to a bacteremia. The most important and typical feature is early bronchopneumonia of an interstitial type associated with peribronchitis. In addition there is often an extensive cerebral edema without local cerebral lesions and a diffuse edema of the optic nerves and spinal cord. Other common disorders include petechial hemorrhages throughout the viscera, microscopic venous thrombi in the lungs and elsewhere, and toxic changes in the spleen and lymph nodes. In a few cases, prior to the onset of apparent critical illness a vague history of irritability, restlessness, refusal of food and fever can be elicited. During this short prodromal stage, occasional vomiting and mild diarrhea are frequently seen. More often the infant is said to have been perfectly well until the sudden onset of his fatal illness. When the disease is well established there is commonly hyperpyrexia, meningism, profuse diarrhea, pharyngitis and uncontrollable convulsions occurring singly or in combination together with the usual manifestations of any severe infection. If debilitation is extreme, the course may be essentially afebrile. Among the eight cases the duration of illness varied from one to six days, with an average duration of sixty hours. The age of greatest susceptibility is apparently from 4 to 7 months. The determination of a pharyngitis or some other acute focus in the upper respiratory tract suggestive of a port of entry is significant. Whenever a critical illness is accompanied by convulsions uncontrolled by sedatives and the spinal fluid examination is negative, acute sepsis should be considered. The interstitial pneumonia so often present seldom gives rise to abnormal physical signs, for death intervenes before an appreciable amount of lung parenchyma has been involved. While positive blood cultures offer the best confirmatory evidence, organisms are not invariably isolated from the blood, and the clinical picture should occupy first place in establishing diagnosis.

Rheumatic Heart Disease—Rosenberg asserts that no disease of childhood is more discouraging to treat than rheumatic heart disease. He reports the case of a boy, aged 9 years, who was having his sixth attack of rheumatic heart disease. After twelve weeks of continuous fever and a persistent accelerated sedimentation rate with no prospect of the infection subsiding, repeated blood transfusions were given and apparently as a result of their use there occurred an immediate slowing of the sedimentation rate and a drop in temperature, accompanied by clinical improvement. While no hope of benefiting the damaged heart valves or restoring the myocardium to normal by blood transfusions is entertained it is the author's belief, based on the outcome in this case and in others referred to that giving blood transfusions may be a method of suppressing an attack of rheumatic fever.

Effect of Benzedrine Sulfate on Hematopoietic System—Because any new drug is potentially dangerous from the point of view of causing damage to the hematopoietic system with resulting changes in the hemoglobin content of the erythrocytes and alterations in the type, quantity and proportions of erythrocytes and of leukocytes, Schube and his associates investigated the ability of benzedrine sulfate to alter these blood elements. The eighty-six subjects used for the study were all physically normal. Six patients received 10 mg of benzedrine sulfate by mouth daily for thirty days. The blood picture was followed at weekly intervals throughout this period and for several subsequent weeks. Seventy patients received 10 mg of benzedrine sulfate by mouth daily for thirty days. Their blood picture was studied from six to twelve months later. Ten patients received 30 mg of benzedrine sulfate subcutaneously daily for fourteen days and the blood picture was studied from six to twelve months later. In the first group of cases (1) there were no significant alterations in the red blood cell counts, (2) the hemoglobin in three weeks of drug administration showed first a decrease and then an increase, (3) the leukocyte count showed no consistent change, (4) the polymorphonuclear count, after an initial drop during the first two weeks, returned to its original level, (5) the number of small lymphocytes decreased in most instances during the first two weeks and remained at the new level throughout the experiment, (6) there was very little change in the number of large lymphocytes, monocytes, basophils and eosinophils and (7) no abnormal or young erythrocytes or leukocytes were found. These changes were not beyond the range of the experimental error of the methods used and were certainly not pathologically significant. In the second group of cases a study of the blood picture from six to twelve months later showed it to be normal. This included the hemoglobin estimation, the erythrocyte, leukocyte and differential counts, and the size, shape and staining reaction of the cells. In the last ten cases a study of the blood picture from six to twelve months later showed no abnormality in any detail.

*Studies in Chemotherapy V Sulfanilamide Serum and Combined Drug and Serum Therapy in Experimental Meningococcal and Pneumococcal Infections in Mice Sara E Brinham and S M Rosenthal —p 685

Studies in Chemotherapy—Brinham and Rosenthal state that sulfanilamide has shown a marked therapeutic action in mice in which a meningococcal infection has been produced experimentally. Twenty strains of meningococci representing types I, II and III have been used. A high percentage of treated animals survived fatal doses of the micro-organisms even when the single drug injection was given two hours after inoculation with the bacteria. The drug has been found to be more effective by subcutaneous injection than by mouth when administered in the same dosage. A comparison was made between sulfanilamide and serum therapy with ten strains of meningococci. With three the drug was more effective, with four the serum was more effective, and with three strains the activity was equal. The combination of serum and drug therapy yielded much better results than either alone. In four experiments in which poor curative effects were obtained with serum or sulfanilamide only, combined therapy resulted in the survival of most of the mice. A synergistic action seemed to exist. The superiority of the combined therapy was likewise demonstrated in mice infected with type I pneumococci. The results suggest that a combination of sulfanilamide and serum therapy in meningococcal and pneumococcal infections in man is worthy of trial.

Etiology of Peptic Ulcer—Carlson and Rivers say that the factor common to all peptic ulcers is that they occur only in tissues bathed by the acid-pepsin gastric chyme. Eroding potentialities promptly develop in tissues that are unaccustomed in their natural physiologic existence to contact with the acid chyme, if by artificial procedures the gastric contents are made to impinge on them. These tissues are more likely to succumb to erosion than are tissues which are normally bathed in the acid gastric juice. The crucial factor of derangement may in such instances exist in disturbances of the tissues themselves. The persistent unmitigated bombardment of tissues by highly acid chyme may break down tissues that have normally intact defense mechanisms. It is not difficult to assume that under such conditions gastric chyme which does not possess unusual erosive characteristics will cause dissolution of tissues, which may lead ultimately to erosion and ulceration. Therefore treatment must not be directed solely to the neutralization of the acid factor but must include some measures to accentuate the defensive mechanisms of these tissues. Even though there may be wide variations in the concentration of acid juice during the day and night, the mucosa is still able to protect itself adequately against ulceration. If, for any reason, this margin

of safety is decreased and lowering of the defensive mechanism of the tissues occurs, ulceration might conceivably develop. In the presence of acid gastric chyme that does not possess unusual erosive tendencies.

Treatment of Bladder Tumors by Roentgen Rays—Pfahler has succeeded in demonstrating both benign and malignant tumors, varying in size from 1 to 8 cm. It is not always possible to make an exact pathologic diagnosis by means of pneumocystography as to whether the tumor is malignant or benign. However, if a tumor is small, sharply defined and pedunculated, and especially if there are multiple tumors, the probabilities are that it is benign. If it is large, irregular on the surface and associated with a broad base, it is probably malignant, and if it is infiltrating in character it is always malignant. If the tumor has definitely infiltrated the wall of the bladder so that it cannot stretch normally, one obtains more definite evidence of a malignant growth than could be obtained cystoscopically. Since urologists state definitely that all tumors of the bladder are potentially malignant, the important matter is to demonstrate the tumor and to remove it by the best means possible, according to the indications in any individual case. The various combinations of treatment in tumors of the bladder have included excision, preceded or followed by irradiation, cystotomy and direct surface application of radium, cystotomy, electrocoagulation and insertion of radium needles or seeds, cystotomy, electrocoagulation and surface application of radium to the base of the tumor, preliminary roentgen therapy, local destruction, subsequently followed by additional roentgen therapy, and high voltage roentgen therapy, with high filtration, supplemented, if necessary, with electrocoagulation of any remnant that does not respond to irradiation. The author has obtained the best results by the last method.

Fallacy of Use of Iodine After Thyroidectomy—Davison and Arnes studied 100 consecutive patients with hyperthyroidism, irrespective of type, from the medical services of the Cook County Hospital and the University Hospital after having been carefully prepared by iodination and supportive treatment. In all of these patients the classic operation of bilateral subtotal thyroidectomy was done in one stage. Fifty patients were given compound solution of iodine after operation.

as in the usual procedure rectally in a dosage of 1 drachm (4 cc.) immediately on the return from the operating room, and from that day on oral administration of 10 minims (0.6 cc.) three times daily. This amount is greatly in excess of that required for iodization. The second group of fifty patients were not given any iodine. Other than this exception, the routine postoperative treatment was the same in the two series, consisting of a minimal amount of 2,000 cc of 10 per cent dextrose given intravenously in each twenty-four hours for two days, and one sixth grain (0.01 Gm.) of morphine administered as was found necessary for restlessness. The postoperative course of both series was judged by the temperature, pulse, respiration and the general toxicity of the patient, on the basis of 1 to 4 plus. The two series are fairly comparable as to average original metabolic rate, average reduction in the rate following the preparation with iodine, and the average number of days required for optimal preoperative improvement. In instances in which the temperature and pulse rate rose disproportionately the administration of continuous intravenous dextrose by dilution produced a steady fall in the temperature and pulse and a general steady improvement in the toxic reaction of the patients not receiving iodine postoperatively. The other series of patients who developed equally high temperature and rapid pulse rates did not respond any more rapidly to iodine and intravenous dextrose. The patients to whom iodine was not administered after operation had an average milder reaction than those who were given iodine. The patients receiving iodine who developed postoperative toxic phenomena did not seem to be influenced any more rapidly by the use of iodine than those who were not given iodine. From this it would seem that the proper attack on untoward reactions following bilateral subtotal thyroidectomy is dilution of the thyroxine in the circulating blood stream by the administration of enteral or parenteral fluids. There is no combination clinically shown to exist between iodine and thyroxine in the circulating blood. If sufficient gland has been removed and if the patient has been adequately prepared before operation, the use of postoperative iodine seems to have no rational basis. The use of iodine is still definitely indicated in such incomplete operations as polar ligations, lobectomy and the removal of discrete adenomas, in all of which cases residual thyroid tissue has been left behind, necessitating further protective iodization.

Old Ununited Clavicular Fractures—Berkheiser believes that the present day treatment of clavicular fractures, particularly in adults leaves a good deal to be desired. He is confident of this because within a comparatively short period he has observed nine cases of ununited clavicular fractures of long standing in adults. Six of these had brachial plexus involvement and seven had to be subjected to open surgical treatment and correction owing to the disability of the patients. Recently one case of fracture of the clavicle with malunion and severe brachial plexus involvement was seen and operative correction was advised. Immediate surgical intervention appears to be indicated if there is marked displacement of the fragments which cannot be aligned and maintained by the usual conservative treatment of reduction and bandaging. In the treatment of old ununited clavicular fractures in adults the use of the tibial bone graft with immobilization is recommended as the method of choice. In order to avoid the disastrous complications of infection, the operative field should have a forty eight hour preoperative preparation and then the operative area should be painted with iodine and alcohol at the time of operation. A semicircular incision is made below the clavicle from a point 1 inch lateral to the sternoclavicular joint extending nearly to the acromioclavicular joint through the skin, subcutaneous fat and platysma muscle. This incision should be made so that the lowest point is at the level of the second rib thus the line of incision will not be directly over the prominence formed by the graft. The periosteum is incised along the anterior superior margin of the fragments and is freed from them by subperiosteal blunt dissection. On the inferior posterior margins of the ends of the fragments there are found long bone spurs. These bone spurs, adherent to the fascial sheath of the nerves and vessels, should be removed with caution. After the ends of the fragments are freed for some distance, the wound is covered with sterile towels. The tibia

is exposed for a distance of 6 inches on its anteromedial surface through a longitudinal incision. The periosteum is not removed from the surface of the tibia, and particular care is taken to leave it attached to the bone. The graft is cut from the tibia with a motor saw, the full thickness of the cortex of the bone being used. After the graft is freed, four drill holes are made in it. The graft is removed from its bed, care being taken not to remove any of the attached periosteum or medullary bone and applied to the anterior superior surface of the clavicular fragments so as to bridge the line of fracture. With the graft in place, drill holes are made in the clavicular fragments to correspond with those in the bone graft. The only bone graft is secured in position by heavy chromic catgut sutures, which are passed through the drill holes in the clavicular fragments and the graft and tied around both. The periosteum muscular attachments and aponeuroses are then closed over the fragments by a continuous suture of strong chromic catgut. The wound is closed without a drain, with a continuous suture for the subcutaneous tissue and with black silk for the skin. The patients are placed on a flat, firm bed without pillows, but with a folded blanket between the shoulders after a snug Velpeau bandage is applied. The sutures are removed in two weeks and then a plaster shoulder spica, which extends from the wrist to the iliac crests, is applied with the elbow flexed to a right angle, thus holding the shoulder upward and backward as far as possible. The patients are then ambulatory for ten weeks, after which the spica is removed provided bony union is demonstrable.

Hypersensitivity and Focal Infection—Weisberger observed that rabbits previously sensitized to horse serum will develop and maintain a bacteremia for from twenty-four to seventy-two hours provided the shock dose of horse serum and the bacteria are inoculated simultaneously into their veins. On the other hand, similar inoculations of horse serum and bacteria into nonsensitized rabbits produce a bacteremia for only one or two hours. This apparent interference with the mechanism for the removal of bacteria from the blood stream was present also in the viscera of the sensitized rabbits. Since it is believed that bacteria are normally removed from the blood by the cells of the reticulo-endothelial system it is suggested that the response of the sensitized rabbits to horse serum is a manifestation of a temporary impairment of the function of these cells. The presence of a transient bacteremia from bacterial inflammatory foci after the intravenous inoculation of horse serum in sensitized rabbits indicates an antagonistic influence on the fixation of bacteria by inflammatory tissue. It is not difficult to understand the removal of Streptococcus viridans from the blood by means of the local inflammatory reaction produced in the sensitized tissues by the inoculation of horse serum. Even a minimal tissue response elicited by normal horse serum or saline solution in nonsensitized rabbits is capable of localizing the bacteria, provided the initial intravenous injection is sufficiently large. The presence of bacteria at the apexes of the teeth may be attributed partially to the localizing effect of the tissue response caused by the introduction of foreign protein into sensitized tissue by way of an exposed dentin or pulp canal. Previous studies have shown that it is possible to shock guinea-pigs with horse serum through the exposed dentin of incisor teeth. The significance of the generalized hypersensitive response in liberating bacteria from dental foci in human dental disease is not known.

Laurence-Moon-Biedl Syndrome—Mutch reports a case showing the complete Laurence-Moon-Biedl syndrome: moderate obesity, hypogonadism and hypospadias, mental retardation, polydactyly, syndactyly, optic atrophy and macular degeneration and lordosis of the lumbar vertebrae. The visual symptoms appeared late, being first evident at the age of 12. Remission occurred, and vision was apparently normal from 14 to 30 years of age. Unlike the usual state of affairs in retinitis pigmentosa, the patient sees best in a dull light and has no difficulty in finding his way about in the dark. At the periphery the retina appears to be normal, only the macular area being affected, this is not surprising when it is remembered that the macular area is photopic in function and has a relatively high light threshold compared with the remainder of the retina, which is scotopic in function, in the eye adapted for darkness it is about a thousand times more sensitive to light than the fovea. The patient's health at the age of 35 is generally good, aside from occasional headaches, impaired vision and a lowered mentality.

Fixation of the Hip Joint—Since 1932 Trumble has obtained fixation of the hip joint by means of an extra-articular bone graft in eight cases of tuberculosis of the hip. The main features of the operation are as follows. The skin and the fascia lata of the thigh are incised in the same line, and the osseous insertion of the gluteus maximus muscle is divided a short distance from the bone. The musculocutaneous flap so formed is elevated enough to expose the tuberosity of the ischium, the femoral shaft and the sciatic nerves. A deep cleft is made in the tuberosity of the ischium with a broad chisel, and a trapdoor opening is cut in the posteromedial aspect of the shaft of the femur a little below the level of the lesser trochanter. A stout free bone graft of the requisite length is cut from the tibia, one end is inserted into a cleft in the tuberosity of the ischium and the other into the medullary cavity of the femur through the trapdoor opening. There were no post-operative troubles and no immediate infection or subsequent breaking down of the wounds in the eight cases. Three of the patients had sinuses discharging on the lateral and anterior aspects of the hip joint at the time of operation, while another had scars of healed sinuses. The sinuses have since healed in two of the cases. The graft united satisfactorily both with the femoral shaft and with the ischial tuberosity in seven cases.

In one case the graft became displaced from the cleft made in the ischial tuberosity soon after operation by some ill advised movement of the limb but united strongly with the femur. Absolute fixation of the hip joint was attained in all but this case. In the years after operation, the increase in thickness and strength of the grafts has been striking and in some of the cases unexpectedly pronounced. In several instances the x-ray appearances are sufficient to show that the grafts, besides acting as distance bars or struts preventing adduction and movement at the hip joint, are transmitting a large proportion of the weight of the body to the femoral shafts. No increase in deformity has occurred in any case. Fracture of the graft occurred in one case, about eighteen months after operation, owing no doubt to the thinness of the graft. Roentgenograms taken at intervals after the fracture show that the fragments have increased in size and density and that there has been some attempt at union. There is no movement clinically appreciable at the hip joint. All but one of the patients were up and about in April 1936. The man in whom the graft failed to unite with the ischium is confined to bed with extensive pulmonary tuberculosis, although the hip disease is quiescent. Six patients have dispensed with all artificial aids to walking, and several have returned to their former occupations.

Spread of Carcinoma by Blood Stream—Patey compared experimentally the spread by the blood stream of malignant disease by the portal and the systemic routes. The tumor used in the experiments was a carcinomatous one growing on the scrotum of a rabbit and successfully transmitted by Brown and Pearce to other rabbits by inoculation into various sites. The experiments showed that under controlled conditions tumor cells reaching the blood stream by the portal vein give rise to metastatic deposits in markedly fewer cases than tumor cells entering through a systemic vein. This observation corresponds to the observations on human malignant disease, which have shown that blood-borne metastases are much more frequent with tumor of the systemic territory, such as carcinoma of the breast and nevocarcinoma, than with tumor of the portal territory, such as carcinoma of the large intestine. The experiments suggest that one of the factors responsible for the diminished incidence in man of blood-borne metastases associated with tumor of the portal territory, as compared with that associated with tumor of the systemic venous territory, is the barrier of the liver. In the present experiments the liver showed deposits in thirteen of forty-four cases in which injection was by the systemic route and in five of forty one in which injection was by the portal route. On a purely mechanical basis, one would expect the incidence of cases with deposits in the liver to be much greater after portal injection, in which all the cells injected enter the liver. It is possible that some of the deposits in the liver following systemic injection represent secondary emboli from deposits in other organs, such as the kidneys. But it is also possible, particularly in view of the work of Foulds on the role of the reticulo endothelial system in the resistance to blood-borne metastasis, that the cells of this system in the liver play a part in the lower incidence of deposits in the liver following portal injection and also in the lower total incidence of deposits. The experiments also confirm the marked selective affinity of certain tumors for certain organs. Thus, in spite of the double barrier of the capillary network of the liver and the lungs, the kidney was the organ most frequently showing deposits after portal injection, just as after systemic injection. Thus, anatomic vascular factors seem to have a part subsidiary to this selective affinity.

Habitual Abortion-Stillbirth Syndrome—Young is of the opinion that the evidence which has become available within recent years is consistent with the view that an important cause of the habitual abortion-stillbirth syndrome is a disturbance occurring in the metabolism of pregnancy, in which a

deficiency of vitamin E is involved. The evidence further raises the question as to the part which vitamin E plays in the gonadotropic progesterone mechanism of pregnancy. Some evidence is adduced for the view that the foregoing considerations may likewise supply one with the missing factor that has been previously postulated to explain the nontoxic recurrence of abortion, stillbirth and accidental hemorrhage in women who are subject to eclampsia and preeclampsia. This evidence is consistent with the view that major degrees of deficiency tend to interruption of pregnancy in the early months without toxic manifestations, whereas if the deficiency is less marked the pregnancy is capable of progressing to the later months with a consequent risk of toxemia. The evidence reviewed in this communication raises the question as to the part played by diet in racial fertility and more especially as to how far changes in the consumption of essential dietetic elements may have contributed to the declining birth rate.

Thoracoscopic Examination and Cauterization of Adhesions—Benjamin believes that every patient treated by artificial pneumothorax for whom a ray examination after the first six or eight weeks shows that the lung is collapsing imperfectly is a potential subject for thoracoscopy and cauterization of adhesions. The presence of adhesions alone is not always an indication for operation. Some adhesions do not prevent a satisfactory collapse. Whether a collapse is satisfactory or not can be judged by the effect of the pneumothorax on the clinical symptoms, such as temperature, cough, the quantity of sputum and the presence of bacilli, and also by the changes in the blood. In some cases, although the patient improves under treatment by pneumothorax in spite of the presence of adhesions, cauterization may have to be done eventually if the adhesion shows a tendency to pull out the lung too early. There must be sufficient pneumothorax space for the manipulation of the instrument. If effusion is present, the fluid has to be aspirated before cauterization. A recent acute onset of effusion is a definite contraindication and thoracoscopic examination should be postponed until the acute stage is over, as manipulation inside the pleura at this stage is likely to cause severe reactions. In only ten of forty patients could all the adhesions be cauterized. Collapse of the lung was increased in these ten after the operation, five patients were much improved and two improved. Tubercle bacilli were present in the sputum of the ten at the time of the operation and disappeared after the operation from the sputum of six. In the remaining thirty patients all the adhesions that were seen could not be cauterized but one or more adhesions were

cauterized in every case. As a result of the operation the collapse of the lung was increased in all. Twelve patients were much improved and nine improved making a total of twenty-one, or 70 per cent, positive results. Tubercle bacilli were present in the sputum of the thirty patients in this group at the time of the operation, and they disappeared from the sputum of fourteen, or 46.7 per cent, after the operation.

Hay Fever—Harley treated forty patients sensitive to grass pollen with extract of grass pollen to a final dose of 100,000 units. Prick and intradermal tests were performed before and after treatment. The prick and intradermal test reactions were both markedly reduced in size following this treatment. The prick test reactions showed a reduction greater than that of the intradermal reactions at the 20,000 unit dose stage of treatment. A number of commercial extracts of grass pollen were tested for skin-reactive potency and very considerable variations were found. Pollen therapy results in a decrease in size of the specific skin reactions provided a sufficient dosage of potent pollen extract is administered. A reaction-inhibiting substance makes its appearance in the serum of patients sensitive to grass pollen after treatment with grass pollen. This substance blocks or inhibits the reactions of normal skin sites to serum-pollen mixtures. The block occurs not between the skin cells and the idioceptor (allergic reagent) but between the latter and the idiotoxin (allergen). The reaction-inhibiting substance apparently acts by attaching itself to the idioceptor, so preventing idiotoxin from uniting with the idioceptor. The attachment of reaction-inhibiting substance to idioceptor does not appear to be very stable. The skin site is found to be fully reactive to pollen extract twenty-four hours later, indicating that the inhibiting substance is removed from the skin in that time.

Microbiology of Canned Foods—Jones intends that the term canned food shall include both foods hermetically sealed in the usual tinne'd iron container and those similarly sealed in glass molds and bottles. The bacteria that are of special interest to the food preserving technologist are roughly grouped as follows: nonpathogenic aerobic spore forming group (which includes the subtilis mesentericus *Clostridium*-simplex *mycoides* *cereus* *megatherium* round terminal spore cylindrical terminal spore and central spored groups), the coccaceae the leucostoc group the anaerobic spore forming bacteria, thermophilic bacteria and the salmonella group. The coccaceae organisms are readily destroyed by heat and should not give rise to any difficulty in efficiently processed cans of food and their presence in the food must be looked on as evidence of

insufficient heat treatment. Organisms of the leukonostoc group are the cause of spoilage in canned condensed milk. They are all facultative aerobes of low thermal death point. The high heat resistance of the spores of anaerobic spore forming bacteria, coupled with their anaerobic propensities, causes them to be more likely to survive canning treatment than organisms of nonsporing character. For this reason the time and temperature of processing, for the sake of safety, has to be based on their possible presence in foods, except in foods of high hydrogen ion concentration, such as canned pineapple. Spores of the nonpathogenic aerobic spore forming group are not especially heat resistant and therefore are of negligible concern to the food canner. Thermophilic bacteria are of great importance in the spoilage of canned foods. Generally their optimal temperature for growth is from 55 to 60 C, and as a consequence they are not only not destroyed but actually encouraged by the washing of utensils, such as trays and tables, with "hot water." Many of them possess spores of a very high heat resistance and infected canned food may spoil in spite of being processed at temperatures calculated to remove even the troublesome spores produced by anaerobes. The salmonella group of organisms are readily destroyed by exposure for a few minutes to a temperature of 80 C, which renders their presence in canned foods extremely improbable. Their toxins are more liable to give rise to trouble, but it is doubtful whether they will withstand 100 C for a period exceeding thirty minutes.

Sulfhemoglobinemia and Methemoglobinemia After Sulfanilamide—Paton and Eaton state that the administration of magnesium sulfate simultaneously with, or within two or three days preceding, the administration of sulfanilamide gives rise in most persons to sulfhemoglobinemia. The formation of sulfhemoglobin takes place very rapidly even after small doses of the drug. In the absence of sulfates large doses of the drug are well tolerated, but in a considerable proportion of persons doses of from 12 to 24 Gm daily result in methemoglobinemia. Some patients may have an increased susceptibility to the drug. The removal of sulfhemoglobin from the blood is much slower than removal of methemoglobin. The former has been detected six weeks after administration of sulfanilamide ceased. The latter disappears in approximately twenty-four hours. Spectroscopic examination of the blood is a more delicate means of detecting sulfhemoglobinemia than clinical observation of cyanosis. Oxygen is of little value in the treatment of severe cases of sulfhemoglobinemia. If the patient's life is in danger, blood transfusion is indicated. In methemoglobinemia oxygen appears to be of value.

Athletics and the Heart—During 1935 and 1936 Cooper and his associates made a series of observations on the oarsmen of the Melbourne University eight, the Ormond College crew and the Scotch College crew. For purposes of comparison a number of outpatients with cardiovascular lesions at Saint Vincent's Hospital have been investigated along lines similar to those used with the oarsmen. It was found that during muscular work appreciable dilatation of the heart does not occur, and that immediately after the cessation of exercise the heart decreases in size. During exertion in the trained man the muscular and respiratory systems are working not only at a more rapid rate but also more efficiently than in the same individual in the untrained state. The effects of training, as seen in electrocardiograms, were not very great. Some of the men of the Ormond crew had electrocardiograms taken before training commenced and when they were prepared for a race. The time interval was approximately three to four months, and in this period the only striking change was an increase in the amplitude of the T wave in lead I. There are appreciable changes in the electrocardiogram after even mild exercise of short duration, such as running up stairs or "touching toes," until the pulse rate rises above 100 per minute. In the adjustment to the increased demands of exercise the pulse rate shows a very rapid rise to the frequency required, for the particular form of exertion, also there is a rapid return toward normal, once the exercise ceases. Extreme variations in blood pressure occur during exercise. The systolic blood pressure and the pulse pressure rise very soon after exercise commences and fall immediately exercise ceases. The fall of blood pressure after exercise is often to a figure below that usual for the individual at rest. There appears to be no parallelism between the pulse rate and the body temperature. The pulse rate may return to normal, while the temperature is still markedly elevated. After prolonged strenuous exertion the blood sugar often falls to a very low figure. The nervous system, the neuromuscular junction and the muscle cell are all closely concerned with the establishment of fatigue during exertion. In no instance of an oarsman who has been rowing for a number of years has the heart been larger than normal and in the majority the heart is smaller than the average for the height and build of the individual. To investigate the late effects of athletics, the records of 100 men rowing for Ormond College between 1885 and 1905 were investigated. Of these men twenty four are now dead (seventeen from natural causes seven from war injuries) and seventy-six men are alive and well. The expected mortality of men of an average age of 21 years during the years in question is 31.8. The men who rowed for Ormond therefore show a lower mortality than the males of the general population.

Preventive Organization in Juvenile Rheumatism—Cove-Smith remarks that in the preventive organization of rheumatism in the juvenile the plan of the London County Council consists of (1) the availability of a sufficient number of beds to provide for an average period of six months treatment for all children showing signs of active disease, (2) the establishment of rheumatism supervisory centers for the pu

pose of early diagnosis of doubtful cases and supervision of quiescent cases, (3) the establishment of a system of supervision of cases after discharge from rheumatism units, (4) investigation and amelioration, if necessary and possible, of the child's home environment and (5) central coordination of the various branches. During the last year the supervisory centers alone have dealt with more than 6,000 cases, while more than 2,000 applications were received from various sources for treatment by the acute units. These figures alone show the vast field covered by this scheme, which, comprehensive as it is, is still susceptible of greater expansion.

Acute Rheumatic Polyarthritides and Concentrated Antiscarlatinal Serum.—Eason and Carpenter assert that the principal disadvantages of salicylate therapy are a high relapse rate and the high incidence of cardiac sequelae. In a series of forty-four cases of acute rheumatic polyarthritides, concentrated antiscarlatinal serum has proved itself an effective form of therapy worthy of extended trial. As compared with salicylates, the advantages of serum therapy outweigh its disadvantages. It is safe to give serum to very ill patients even when suffering from grave carditis. The immediate effects of serum are sufficiently satisfactory to justify its wider use with a view to determining its effect on the incidence of cardiac sequelae, which is the only part of the rheumatic syndrome dangerous to life. It is unlikely that the effects of antiscarlatinal serum on acute rheumatic polyarthritides are entirely specific. Similar effects are reported with nonspecific protein therapy. A brief series of controls, showing a high relapse rate, indicate the possibility of combining a nonspecific element and a specific element in concentrated antiscarlatinal serum. There is no evidence that either serum therapy or the withholding of salicylates was a contributory cause of death in the three fatal cases of the forty-four treated with antiscarlatinal serum.

Skin Sensitivity in Asthma.—Pearson believes that the knowledge of the frequency of reactions to intradermal injections of horse serum in healthy subjects is essential not only in estimating the practical value of skin tests but also in forming a true conception of the part played by the presence of sensitivity in the production of asthma and allied conditions. It was to obtain information of this kind that he carried out intradermal tests under the same conditions on a series of control subjects (342) and of asthmatic patients (293) using extracts of five substances: horse dander, chicken feathers, wheat, egg white and dilutions of pure horse serum albumin. Sensitivity to common inhalant substances occurred with considerable frequency among "control" subjects. The percentage of positive reactions and the proportion of large reactions are considerably greater among a corresponding group of asthmatic subjects. A group of persons who gave a history of having experienced some atopic condition in the past or in whose family such a condition was reported to be present, showed a greater proportion of skin reactions than a group who gave no such history and was intermediate between these and the asthmatic group. Sensitivity to inhalant substances was found to be greatest in subjects between the ages of 15 and 30 years. This was found to be true for the asthmatic and control groups. Sensitivity to more than one extract occurred frequently in all groups and it was exceptional to find subjects highly sensitive to one substance who failed to react in some degree to extracts of other substances.

Extrasystole and Vagus Action on Heart. E. de Somer—p. 565

Anemias of the New-Born.—Pehu and Noël share the opinion of those who think that real anemia is rarely diagnosed in early infancy. Except for rare instances, the new-born infant is little exposed to general infections, septicemias or toxemias that would have an untoward influence on his blood. As regards the behavior of the hematopoietic system, the authors distinguish between secondary and idiopathic anemias. The underlying causes leading to the impairment of the infant's blood are primarily internal and external hemorrhages from the digestive tract, the umbilicus or the adrenals. Of the infections giving rise to anemia in the new-born, first place is to be given to congenital syphilis and congenital malaria. The blood of these patients returns to an embryonic stage in which proerythroblasts and erythroblasts can be observed, but rarely megaloblasts. The composition of infantile blood may also be impaired if during pregnancy the mother has received insufficient or inadequate food, or food deficient in iron. But anemia of the mother has only seldom an untoward influence on the blood of the fetus. The so-called idiopathic anemia appearing to be primary or congenital because no underlying cause can be found for it, was first observed by Ecklin in 1919. It must be differentiated from grave familial icterus of the new-born and from fetoplacental anasarca. This anemia makes its appearance about seven or eight days after birth. The patient is usually of a healthy disposition with normal stools and urine but with a slightly enlarged spleen and liver. The peripheral blood and that of the liver and spleen shows an abnormal quantity of erythroblasts. But to include this disease among the erythroblastoses is not yet quite well founded, especially because little information has been received from analysis of the bone marrow of these patients. It remains also to be determined whether this entire anemic syndrome is or is not the result of deficient maternal nourishment.

- *Dangerous Universal Donors. E. Balgarnies and L. Christiaens—p. 649
Generalized Herpes with Fever. J. Minet and P. Dupire—p. 669

"Dangerous" Universal Donors.—Balgarnies and Christiaens, following reports by American and European authors, made the observation that blood transfusions from certain universal donors (group O) may be injurious. This seems particularly true of blood rich in agglutinins. A case of hypoplastic anemia is cited in which the first transfusion of 150 cc of group O was well tolerated, but the second from another donor of the same group was soon followed by an alarming shock. But while the first donor had a low proportion of antibodies, the blood of the second was rich in antibodies and the authors attribute the shock to the latter condition. A third transfusion of group A was well tolerated. Of 217 cases of hemolytic shock, Hesse found forty-six coming from group O, in which the receiver may or may not belong to the same group. Some are also complicated by nephropathies. But the authors are not of the opinion that capillary thromboses or emboli are the direct cause of the renal disturbances. On the basis of the works of Hesse and Filatov of Leningrad they attribute the cause to hemolysis during which the destruction of red blood corpuscles gives rise to certain depressing substances which induce spasm of the blood vessels. This results in the enlargement of the capillary network, slowing of blood circulation and lowering of blood pressure. The heart action is diminished, owing to its incomplete diastolic filling. The severity of the shock may eventuate in renal abreaction or even death. The quantity of blood transfused and the lesser or greater integrity of the reticuloendothelial system determine the degree of hemolysis. To determine the proportion of antibodies, the authors use Schiff's centrifuge technic. Five-tenths cubic centimeter of serum is diluted in geometrical progression ($\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$) to which is added 0.5 cc of a 5 per cent solution of erythrocytes of standard A or B. The mixture is

stirred and then left to stand for fifteen minutes. Then it is slowly centrifugated for thirty seconds and immediately examined. In case of doubt, another reading is made half an hour later. The authors thus found a preponderance of anti-A-bodies in serums of group O, in which the "dangerous" donors are included to about 4 per cent. But it is not the proportion of agglutinins alone that constitutes the "danger." It depends likewise on the dilution and the humoral constitution of the blood given. It has therefore been advised to test universal donors and to restrict those whose plasma is particularly rich in antibodies, universal donors are contraindicated in severe anemias in which the corpuscular resistance is decidedly diminished and in cases of blood disease or renal insufficiency. But the tests in their present form are not particularly reliable, and universal donors should be reserved only for urgent cases. The best treatment of shock is the injection of homologous blood, of which a few cubic centimeters may be sufficient.

Decapsulation of Kidney.—Ciminata resorted to decapsulation of the kidney in a group of eight patients suffering from nephritis or nephralgia. Pain in the kidney uncomplicated by nephritis disappeared after the operation, which caused only a temporary relief or none at all in nephritis and glomerulonephritis. The author regards decapsulation of the kidney a partial sympathectomy which induces favorable modifications of the circulation and structural conditions of the kidney with consequent improvement of the renal functions. Freeing the kidney from perirenal adhesions by decapsulation results in suppressing painful spinal stimulation to the organ, which also plays a part in stopping renal pain.

Hypercholia in Feces in Bronchopneumonia of Infants.—According to Galeotti-Flori, the presence of excessive excretion of bile in the feces is a common occurrence in the course of bronchopneumonia in infants. It is so common that an early diagnosis can be established when the symptoms are still slight. The author states that alterations of the blood due to the pulmonary pathologic condition and hemolysis caused by bacterial toxins, with consequent bilirubinemia, play a part in the establishment of an increased elimination of bile. The main causal factor, however, is a reaction of the liver to circulatory, toxic and bacterial stimuli. During reaction the organ secretes more bilirubin than it does normally and eliminates bilirubin recently formed as well as that stored in the structure. The greater the enlargement of the liver the darker the color of the feces and the greater the amount of bilirubin they contain. The amount of bilirubin in the feces has no relation to the intensity and evolution of bronchopneumonia, but it is especially related to the secretory and chologenic reaction of the liver. The elimination of bile acids parallels that of bilirubin. The author performed daily determinations of bilirubin in the feces of twenty-nine infants suffering from bronchopneumonia. In all cases the amount of bilirubin eliminated was increased in comparison to that eliminated by infants suffering from diseases other than bronchopneumonia.

Disorders of Fat Metabolism After Splenectomy.—Zancan found that experimental splenectomy in dogs induces transient disorders of the fat metabolism. Five or ten days after splenectomy the total lipids, total cholesterol and the cholesterol esters and phosphatides are increased, the neutral fats are decreased and the free cholesterol in the blood is unchanged. The disorders of the fat metabolism are attenuated twenty days after splenectomy. One month after the operation the fat metabolism is normal. The fat fractions show oscillations forty-five, sixty, seventy-five and ninety days after splenectomy, which are due to physiologic changes in the fat metabolism due to splenectomy. The body weight, the amount of total proteins in the blood and the chromocytometric values show slight variations after splenectomy which are not related to the operation. The transient disorders of the fat metabolism after splenectomy seem to be due to rupture of the equilibrium of the sympathetic nervous system with consequent increase of the liver function in its relation to the fat metabolism.

Roentgenologic Diagnosis of Placenta Praevia.—Robecchi and Zocchi used Ude and Urner's technic in thirty-four cases in which the presence of placenta praevia was suspected. The original technic was reported in the *American Journal of Obstetrics and Gynecology* (29:667 [May] 1935). The method is based on the relation between the contour of the head of the fetus, in cephalic presentation, as a landmark and the shadow of the urinary bladder, which is rendered opaque by means of the injection of a contrast medium. According to statements of the original authors, the contour of the fetal head in the lower uterine segment is continued in the shadow of the bladder in the last three months of normal pregnancy, whereas a free space caused by the placenta separates the fetal head from the shadow of the bladder in roentgenograms of cases of placenta praevia. Robecchi and Zocchi state that the method is of diagnostic value if pregnancy has evolved beyond the seventh month. Before this time roentgenograms with the characters of those showing central placenta praevia may be obtained in normal pregnancy. The space between the contour of the fetal head and the shadow of the bladder should be more than 1 cm in width, at least to have diagnostic significance. Separation of the cephalic and vesical shadows by a placenta praevia takes place regardless of the point of insertion of the latter at the anterior or posterior aspect of the lower uterine segment. The method has no value for the differential diagnosis of grave detachments of normally inserted placenta and for placenta praevia if the fetus is in the podalic presentation.

Roentgen Irradiations in Small Doses in Deficient Menstruation.—Robecchi states that roentgen irradiation in small doses over the ovaries in menstrual disorders is harmless. He resorted to the treatment in a group of eighteen cases. The irradiations were given with a Duoval apparatus with a tension of 170 kilowatts, an intensity of 3 milliamperes, a filter of 0.5 mm of copper and 3 mm of aluminum and a hemivalent layer of 0.8 mm of copper at a skin focal distance of 40 cm. The irradiations were superficially given on a circular field 13 cm in diameter, over the ovarian region. A dose of 125 or 150

roentgens fractionated in two treatments with one week's interval between the first and second irradiations were administered. In rare cases the irradiation was repeated six months later or a superficial hypophyseal irradiation, of 175 roentgens, was given through two temporal fields. According to the author, the treatment gives fairly satisfactory results in primary scanty menstruation and amenorrhea. The best results are obtained in patients under the age of 25, when the disease is of recent development (less than three years) and when there are no grave organic lesions of the internal genitalia. The fear that roentgen irradiations of small doses may cause irreversible harm to the sex functions or to the fertilized egg are unjustified. The irradiations destroy the altered follicles, but cells of great vitality are ready for the fecundation process. The author's experience with the treatment dates back fifteen years. He shows the advisability of resorting to the treatment more frequently.

*Skin Reactivity of Men to Killed Tubercle Bacilli E. Carlinfanti—p. 262

Reactivity of Skin to Killed Tubercle Bacilli—Carlinfanti made a comparative study of the reaction of the skin to killed tubercle bacilli and to old tuberculin in a group of about 100 cases, including pulmonary and other forms of tuberculosis and nontuberculous diseases. The tubercle bacillus preparation consisted of an ointment made up with tubercle bacilli, killed by heat at 158 F. An amount equivalent to the size of a pea was left in contact with the skin of the anterior aspect of one arm, whereas old tuberculin was epidermally or intracutaneously administered in the other arm. In 76 per cent of the cases the reaction of the skin to killed tubercle bacilli was positive. The reaction and its intensity for either antigen were different. Some patients with a slight reaction or no reaction at all to tuberculin reacted to killed tubercle bacilli. According to the author, the diagnostic and prognostic significance of the skin reaction to the ointment of killed tubercle bacilli is more reliable than that of old tuberculin. The dissociation of the skin reaction to the antigens shows that the allergic reactions are selective for the different antigens contained in tubercle bacilli and that patients in a condition of allergy may give negative reactions to tuberculin. The lack of a positive skin reaction to tuberculin does not rule out the existence of allergy, which may be selective in the given case. The existence of selective allergy is of importance in relation to the pathogenesis of tuberculosis.

Diverticulosis of Small Intestine G. Bignami—p. 422

Radiobiology and Radiothanatology—Paltrinieri made microscopic studies of the skin of cadavers which was previously subjected to infrapenetrating radium irradiations and soft roentgen irradiations. He concludes that the cells of cadavers react to the irradiations during the first hour after death. The reaction is active, biologic and different from the passive action of other physical or chemical agents of caustic action. The action of the irradiations both on living and on inorganic matter, is of a physical nature. It is related to phenomena of ionization, luminescence and secondary irradiation. The phenomena, and hence the reaction, are different in living and in inorganic matter owing to the fact that the former is able to react with a cytolytic reaction to the physical stimulation from the irradiations whereas the latter is not. The radiosensitivity of the cells depends on the life of the cells and on the intensity of their metabolism. It is conditioned by the intracellular formation of radiolabile physicochemical structures in a reaction of both the cells and their metabolism to the physical stimuli. The action of the irradiations on the cells is direct (from the

irradiation) and indirect through the local reaction of blood and cellular fluids in the irradiated territory. The protoplasm is just as important as the nucleus in the development of radiosensitivity. The irradiations act by stimulating groups of cells to reaction with consequent active necrobiosis of the cells themselves. The reaction is elective during the first half hour after death and does not take place one hour later. This fact can be of use in medicolegal procedures for differentiating actual from apparent death and determining the hour at which death took place in a given case. The author states that the irradiations with primary beta and gamma rays of radium have an active action on cells which survive after death.

Question of Takata Reaction F. Hahn—p. 710

Influence of Venesection on Vital Capacity of Lung—Budelmann says that the vital capacity of the lung is an indirect but reliable measure for the blood perfusion of the lung. Pulmonary congestion by blood is accompanied by a reduction in the vital capacity. This is caused by an impairment of the respiratory mechanism of the lung, which in turn is the result of a pulmonary rigidity and of a corresponding increase in the intrapleural pressure. The decrease in the vital capacity is explained by a reduction in the air reserves of the lung. Not only does measurement of the vital capacity of the lung reveal a reduction in the vital capacity in case the lung is overfilled with blood, but a reduction in the blood content of the lung manifests itself in a corresponding increase in the vital capacity. It is well known, for instance, that the vital capacity increases following venesection in cases of chronic and acute pulmonary stasis and after digitalis therapy in cardiac insufficiency with pulmonary stasis. Thus it can be said that the blood perfusion and the air content of the lung show an antithetical behavior. The author further describes observations on the action of venesection on the vital capacity of the lung in healthy subjects. In healthy students and in patients without heart disease who had practiced spirometry and in whom a normal value had been computed, the vital capacity was measured following a venesection in which from 500 to 1,000 cc of blood was withdrawn. The venesection was followed in all cases by a noticeable increase in the vital capacity, and the persons stated that their breathing was freer and deeper. But, whereas in cases with a pathologic overfilling of the lung the increase in the vital capacity corresponds to the quantity of blood that has been withdrawn, this is not always the case in healthy persons. Moreover, the increase in the vital capacity of healthy persons is observable for only a short time (about one hour) after the venesection.

Muscular Phenomenon in Focal Infection—After citing his earlier histologic studies on the various forms of muscular atrophy, which revealed that the disorders of connected fields of muscular fibers are the result of the impairment of the ganglion cells of the anterior horns of the spinal cord or of the cells of the motor nuclei of the cerebral nerves, Slauck directs attention to the symptom of "muscular fibrillation." He shows that in the rheumatic conditions in which toxic foci play a part the musculature of the inside of the foot and of the calves of

the legs shows fibrillation. Moreover, the muscles of the hand and those in other localizations may likewise exhibit the symptom of fibrillation. The author emphasizes that this symptom will enable the practitioner to determine whether a focal infection exists and whether there is dissemination of the toxin into the cerebrospinal fluid canal. In all cases in which muscular fibrillation is detected, the practitioner should see to it that a thorough search is made for toxic foci.

 Pneumonia like Course of Pulmonary Tuberculosis in Patients with Diabetes G. Dilyannis—p. 668
 Prontosil in Infections of Urinary Passages A. Weiser—p. 674

Limitation of Carbohydrates in Treatment of Migraine—In studies on the dehydrating and therapeutic effects of diets with a restricted carbohydrate content, Porges observed that migraine is often favorably influenced by such a diet, just as many cases of migraine are favorably influenced by a salt-free diet. He treated a number of patients with migraine by putting them on a diet with a limited carbohydrate content. Some of the patients had been treated previously with restriction of the sodium chloride intake, without adequate success. In these cases the author added the carbohydrate limitation to the salt restriction, in other cases he at once started with limiting both the salt and the carbohydrate intake and in still others he restricted only the carbohydrate intake. The therapeutic effect was generally favorable. The best results were obtained by restricting both the salt and the carbohydrate.

Tuberculin Sensitivity of Skin—Sylla and Rothe point out that, although the old tuberculin reaction is of definite diagnostic value in children, its reliability is still disputed in adults. For this reason they decided to investigate the diagnostic value of the old tuberculin test in a large number of nontuberculous and tuberculous adults. Because exact dosage is possible in the intracutaneous test, the authors employed the Mendel-Mantoux test rather than any of the cutaneous tests. They used Koch's old tuberculin in solutions of 1:10,000 and 1:100,000. These solutions were made with distilled water rather than with physiologic solution of sodium chloride. The tuberculin tests were made on 1,516 patients. Of these, 908 were free from tuberculosis and 608 had tuberculosis. It was found that with a tuberculin solution of 1:10,000, in a quantity of 0.1 cc, 21.8 per cent of positive reactions were obtained in the nontuberculous patients. On the other hand, 25.35 per cent of the tuberculous patients had negative reactions. If tuberculin dilutions of 1:1,000 are used in adults, there are almost 100 per cent positive reactions. If positive reactions are obtained with dilutions of 1:10,000 and higher, the sensitivity of the skin is increased. The negative outcome of the skin reaction does not permit conclusions regarding the allergic state of certain organs. The existence of tuberculosis cannot be demonstrated by means of an old tuberculin test. However, it may prove valuable for the desensitization treatment not only of tuberculosis but also of other disorders in which there exists a hypersensitivity to old tuberculin and which are of a predominantly allergic character (asthma, chronic arthritides and so on).

 *Fractures of Ungual Phalanx of Fingers A. Perschl—p. 810
 *Importance of Tryptophan Test for Diagnosis of Tuberculous Meningitis R. Pongratz—p. 814

Surgical Treatment of Painful Calcaneal Spur—Spitz shows that it is not merely the contact with the floor which makes the calcaneal spur painful, but particularly the traction on the plantar fascia and on the flexor digitorum brevis, which

have their point of attachment at the site at which the calcaneal spur develops. In persons who have a considerable amount of excess weight, the traction at this point is especially severe and painful. The operation recommended by the author severs subcutaneously, by means of a tenotome, the fascia and muscle, which are attached at the site of the spur. Eight days after this simple operation, the patients were able to step on their foot without feeling pain. The operation was performed in seventy cases, in two of which it was a failure. In discussing these two failures, the author stresses the importance of the differential diagnosis, pointing out that merely the roentgenologic demonstration of a spur does not justify the intervention but only the painfulness of the spur, which has been demonstrated by careful local examination.

Fractures of Ungual Phalanx—Perschl cites cases and reproduces roentgenograms which demonstrate that, in case of fracture of the unguinal phalanx, it usually takes from four to six months until the part of the bone which has been torn away is again united with the terminal phalanx. The pain, however, disappears at the latest after four weeks and the working capacity likewise has been completely reestablished at this time, in fact, some hard-working persons do not interrupt their work at all in the presence of such fractures. The author directs attention to this belated union in fractures of the unguinal phalanx in order to prevent the premature removal of the detached bone and to avoid unnecessarily prolonged invalidism.

Tryptophan Test in Diagnosis of Tuberculous Meningitis—Pongratz demonstrates that the tryptophan test is of great value in the differentiation between tuberculous meningitis and all nonpurulent meningitides and encephalitides. The tryptophan test is already positive during the beginning stage and thus permits a diagnosis during the prodromal stage. Moreover, the technique is simple and requires little time, so that the practitioner can perform it.

 *Hepatic Function and Its Significance in Tuberculosis I. V. Balanescu and S. Oeriu—p. 377

Diaphragmatic Paralysis After Tuberculous Changes—Muller says that today diaphragmatic paralysis is usually diagnosed by means of roentgenoscopy, which reveals reduction in the motility and in the tonus of the diaphragm. The diaphragmatic hypotension usually becomes manifest in an elevation of the diaphragm, and, in case of a more severe paralysis, it is expressed in a paradoxical respiratory movement. The tuberculous processes that cause diaphragmatic paralysis are especially those of the hilus and its surroundings, that is, those which impair the phrenic nerve. However, in order to decide whether an impairment of the phrenic nerve is caused by a tuberculous process, the paralysis should develop during the process and later perhaps disappear again. To be sure, this is rarely possible and a probability diagnosis must be accepted. A paralysis of a different origin cannot be excluded if it does not disappear again. The author cites cases in which the etiologic diagnosis was impossible. He states that the incidence of typical diaphragmatic paralysis in tuberculous processes of the hilus is not definitely known but that at this clinic, at least, diaphragmatic paralysis was less frequent in these tuberculous processes than in diphtheria and poliomyelitis. However, he regards the milder forms of phrenic lesions as comparatively frequent in cases of tuberculous processes of the pulmonary hilus. He describes several cases in which appearance and disappearance of paralysis could be observed. In one child a paralysis developed twice on the same side. Successive exacerbations may also be observable in the paralytic process. In two instances, good motility of the diaphragm was observed in the presence of considerable elevation.

Hepatic Function and Tuberculosis—After discussing the value of the galactose test in the detection of hepatic disorders, Balanescu and Oeriu describe their studies on sixty

patients and ten healthy persons. They made comparative galactose tests with Bauer's method and with one devised by themselves. They place the night urine, which has been voided at 7 a. m., into a container marked A₁. Then the patient is given a galactose solution, which is prepared by dissolving in 200 cc of warm water a quantity of galactose equal to 0.5 Gm for each kilogram of body weight. The patient is not permitted other food during the subsequent two hours. The urine voided during the two hours following the intake of galactose is placed in a container marked A. Since urine contains a number of substances that reduce potassium permanganate solution, a quantity of thirtieth normal potassium permanganate solution sufficient to effect reduction is added to the urine. In healthy persons less potassium permanganate solution is required for the urine in container A than for that in container A₁, in patients with hepatic disturbances, however, more solution is required for A than for A₁. The reaction can be expressed in the following manner: A smaller than A₁ equals negative galactose reaction, A larger than A₁ equals positive galactose reaction. A tabular report indicates that the method developed by the authors is more sensitive than the Bauer method, for it discloses even the mild and incipient forms of hepatic disorders. Moreover, it requires less time and is thus less trying for the patient, and the laboratory technic is simple. The authors studied the hepatic function of tuberculous patients, particularly, in order to detect whether gold therapy causes hepatic diseases. They found that, although gold therapy does not as a rule produce hepatic disorders, it usually exacerbates an existing hepatic disorder. They advise that the hepatic function be tested before gold therapy is begun.

Deformities of Urinary and Sex Organs. B. Szendi. —p. 1234

Fatalities After Implantation of Ureter into Intestine—Von Mikulicz-Radecki and Krauspe review the literature on the transplantation of the ureters into the large intestine according to the method of Coffey. They disagree with the authors, who regard this method as entirely without danger, for although the immediate results may be favorable, the later results often are not. They demand that, before resorting to Coffey's operation, the gynecologist should consider the following: 1. The transplantation of the ureters into the intestine results in an unphysiologic condition, which, in spite of the geniality of Coffey's technic, involves dangers for the kidneys. It does not produce an ideal condition but is only a makeshift, which should be resorted to only if all other methods of plastic reconstruction on the urethra and bladder have failed. 2. Coffey's operation is indicated chiefly in exstrophy of the bladder and in vesical carcinoma. In these conditions, Coffey's operation accomplishes favorable results and the reports about these

induced the gynecologists to resort to this operation also in gynecologic disorders. However, there are fundamental differences in exstrophy of the bladder, the kidneys are healthy and the same may be the case in vesical carcinoma, or, if not, the transplantation of the ureters is intended only for temporary relief, the ultimate prognosis of vesical carcinoma usually being unfavorable. But if the urinary incontinence is caused by vesicovaginal fistulas or by defects in the urethra, the ureters, renal pelvis and even the kidneys have usually become involved in an ascending infection which would be further promoted by the transplantation of the ureters into the intestine, even if by a special technic the infection from the intestine should be prevented. Following the description and evaluation of the different technics of Coffey's operation, the authors cite late fatalities after this operation, some of which were reported in the literature and two of which they observed.

*Secretagogue Action of Extracts of Salivary Glands. Humoral Genesis of Gastric Secretion. R. Boller and W. Pilgerstorfer. —p. 231

Leukemias with Tumor-like Growth—Fleischhacker and Seyfried point out that some authorities still insist that leukemic disorders should be classified with the tumors, but that the greatest majority regard the leukemic metaplasias and infiltrations as essentially different from tumors. However, the literature reports cases in which tumor-like formations developed in diseases the leukemic character of which had been definitely established. In lymphomatosis, particularly in its aleukemic forms, there is a tendency to the development of tumor-like infiltrates in the skin and in the mucous membranes. In some cases these are the only symptoms, in that the typical enlargement of the spleen and lymph nodes develops later or not at all and the leukemic blood picture is entirely absent. If leukemia takes this course, it is necessary to consider in the differential diagnosis also the possibility of a lymphosarcoma. The differentiation of lymphosarcoma may encounter considerable difficulties. However, if the examination of blood and bone marrow fails to clarify the diagnosis, the puncture of the diseased lymph nodes or of the tumor may aid in the decision. In this connection the authors cite a case in which exploratory excision from the retroperitoneal and inguinal lymph nodes did not permit a differentiation between lymphogranulomatosis and lymphosarcoma, but puncture of the lymph nodes revealed the typical tumor cells. The authors further describe and discuss cases of leukemia in which tumor-like growths were observed. In the first case an operation was performed on the basis of the erroneous diagnosis of medullary carcinoma, but later the typical aspects of aleukemic lymphomatosis were observed. This case indicates that a hematologic test should be made even in apparently clear cases and it also shows that histologic examinations may produce erroneous results. In a second case the breast had been amputated on account of a rapidly growing tumor but the histologic examination revealed a lymphatic leukemic hyperplasia. In this connection the authors point out that a survey of a large hematologic material will disclose lymphomatoses which are accompanied by lymphatic-leukemic infiltration of the mammary gland. Following the discussion of several other cases, they conclude that a knowledge that leukemia may be accompanied by tumor formation is not only of scientific interest but also of importance for the correct treatment for it is inadvisable to subject patients with leukemia to surgical interventions.

Secretagogue Action of Salivary Glands—Boller and Pilgerstorfer say that in former studies on extracts of the salivary glands they were able to show that a secretion of gastric juice takes place following the injection of an extract from the parotid and the submandibular glands. They point

out that substances which act on the gastric secretion were detected also in other organs of the digestive tract. Comparative tests were made to determine whether the secretagogue substance of the salivary glands exerts the same action as the substances from other organs. Moreover, extracts from organs outside the digestive tract were tested for their secretagogue action. In summarizing their observations, the authors say that extracts of the salivary glands of cattle contain a substance which, when administered by way of the blood stream, stimulates the secretion of gastric juice. This substance, although exerting a histamine-like effect, is not identical with histamine but, presumably, is identical with the gastrin that was discovered by Edkins. The comparison of the extracts of the salivary glands with those of the mucosa of the stomach, the duodenum, the colon and the rectum revealed that these different extracts vary in potency. Most potent is the extract of the duodenal mucosa, then follow those of the stomach, the salivary glands, the colon and the rectum. With the exception of the liver, the organs outside the digestive tract do not contain secretagogue substances.

Pulmonary Endocarditis with Multiple Lung Infarcts Case W. Edgren —p. 151

Significance of Premature Delivery—Brander says that in his material of 370 premature children 14 per cent have an intelligence quotient above normal, 46 per cent normal and 527 per cent below normal. The main factors leading to mental deficiency in premature children are the low birth weight, birth complications (in which he includes not only complications such as asphyxia and abnormality in presentation but also complications in pregnancy [eclampsia and syphilis] and grave operative interventions in connection with delivery) and hereditary psychic taints. Of his cases 230 were without birth complications and poor psychic heredity, sixty-six with birth complications, fifty-four with poor psychic heredity but not birth complications, and twenty with both. The mental development was most favorable in the first group and least favorable in the last. Among the anomalies in delivery, primary or secondary pelvic presentation is of greatest significance in the mental development of the premature, because of its relatively high frequency in premature births. Of the psychic disturbances in heredit, alcoholism is most important in this material. The author presents tables to show that in the first group of 230 cases different degrees of defective mental development are due to different degrees of the same cause—birth weight, duration of delivery, rickets and enlarged tonsils, respectively. He says that not only the primary mortality and the percentage of pronounced cerebral defects can indicate the intensity of intracranial birth traumas, the frequency of milder degrees of intellectual inferiority should also be considered. Study of the causes and prophylaxis of the less marked forms of mental defects seems to him fully as important as that directed to the gravest forms of mental deficiency, since the former undoubtedly occurs more often, and there may further be a question as to who are more detrimental for society, the mildly defective at large or the hospitalized idiots.

*Inflow of Duodenal Contents into Bile Ducts C. I. Baastrup —p. 443

Inflow of Duodenal Contents into Bile Ducts—Since in Baastrup's case of entrance of contrast substance into the bile ducts jaundice had appeared after passage by the rectum of a stone of the size of a hazelnut, and since the choledochus was slightly irregular, he considers it likely that the stone had passed by way of the ampulla of Vater and not through a

fistula between the gallbladder and the duodenum and that an insufficiency of Oddi's sphincter had resulted. To the causes for inflow of duodenal contents into the bile ducts named by Titone he therefore adds insufficiency of Oddi's sphincter after passage of a calculus. He also says that, while he has seen only three reports of roentgenologically demonstrated air in the bile ducts, the phenomenon is not particularly rare.

Rectal Hematoma—C. Avitaminosis S. With —p. 521

Surgical Treatment of Leukokeratosis of Penis—Hansen excises all the affected tissue in healthy tissue and stresses preservation of the skin of the prepuce, sewing it to the corona of the glans, so that part of the prepuce is kept. In cases with disorder of the glans he excises the thickened parts simultaneously with extirpation of the frenulum, and in six cases he resected the outermost part of the urethra at the same time and sewed the edges to healthy tissue, he thinks that the absence of more marked bleeding is due to his not having excised radically enough to reach healthy tissue, in a man, aged 77, there was recurrence after three years. In three cases with disturbance of the glans, radical treatment was given by electrocoagulation. He finds the results of his treatment of leukokeratosis of the penis satisfactory and recommends his procedure as the normal method. The observation period has been up to eight years. Carcinoma has not developed in any case, and the patients have been freed from their discomfort almost immediately after operation. After-examination of twelve patients showed no recurrence of the keratosis with localization on the prepuce and the glans. The five after-examined cases of urethral keratosis were also without recurrence. The postoperative cicatricial changes presented in three instances were easily treated by simple dilation with a bougie. He advises against incomplete operation for phimosis, which is followed by recurrence. Twenty-four cases are described.

Pneumo-Arthroradiography of Knee Joint Especially Technique O. Scheibel —p. 548

Osteochondritis Dissecans with Mouse Formation in Semilunar Bone J. Bak —p. 556

Heart Lesions Due to Trauma—In twenty-two out of thirty-two persons who died up to sixteen days after trauma due to powerful blunt force, mostly in automobile accidents, Munck found changes in the heart believed to be connected with the trauma. There were grave changes, especially in the cases with direct lesion of the thorax. Scattered small hemorrhages in the myocardium predominated. On microscopic examination there were also frequently subpericardial and subendocardial bleedings seen to extend into the underlying musculature. Distention of blood vessels, in spots or more diffuse was often seen, mainly in the small veins and in capillaries and often in the combination of dilated veins and contracted arteries. The author believes that, if certain patients had survived these hemorrhages might have affected the heart function and later caused clinical symptoms. Nine cases are described.

THE FUTURE OF MEDICINE

CHAIRMAN'S ADDRESS

J H MUSSER, MD

NEW ORLEANS

It is rightly said that he who would attempt to foretell the future is either foolhardy or an ignoramus foolhardy because he lays himself open to future exposure of his fallibility, an ignorant person because it is obvious that he has no knowledge of the past and what has gone before. If this is true with regard to forecasting social, economic, militaristic, political or professional events and trends, how emphatically true it is in reference to any attempt to foretell what may take place in economic or scientific medicine in the approaching distance.

In the field of medicine, small and seemingly inconsequential discoveries or observations have effected totally unexpected changes in the science and practice of the profession. These developments brought about profound alterations in subsequent medical practice which the prophet of the day most assuredly could not, or would not, have appreciated. Striking examples might be cited. When Auenbrugger applied a physical principle well known to the mechanics of his day to the human body and Laennec made use of a hollow tube the better to hear the sounds generated in the chest, diagnosis of diseases above the diaphragm soon became a matter of relative exactitude and not a matter of speculation. Until the time of Louis, medical observation consisted of the recital of what appeared in the occasional and sporadic case. When this great clinician initiated statistical methods of analyzing disease and disease trends in a large series of cases he also effected a profound advance in medical knowledge. The science of immunity began with a chance observation of a keen-witted country doctor. What has been accomplished by the studies of Pasteur, by the hard fought but eventual triumph of Lister, needs no recounting, nor must it be forgotten that present day diagnosis, and to a limited extent treatment, is tremendously dependent on the random observation of a German physicist, Roentgen, that certain rays of light, which developed in a peculiar type of tube, were able to pass through practically any substance save a few of the heavy metals.

If such scientific studies and discoveries, seemingly trivial at the time of their conception, can bring about revolutionary changes in the art of diagnosis and treatment of disease, how can the astounding upheavals in the political world that have taken place since the World War have anything but a tremendous repercus-

sion on the social and professional life of every physician? In the last few years almost elemental changes in our form of government and in the care of the indigent ill presage still further alterations in our methodology of practice. Changes in mode of practice and in obtaining a professional living by the individual are truly predicated on mass change in government and in social outlook or point of view. Only scant suggestions of what might happen socially and economically in 1937 were presented to the physician of twenty-five years ago and but slight reason would he have had to foretell how rapidly medical practice would be changed in subsequent years.

Having pointed out the fallacies of prognostication not based on historical evidence and the difficulties of the soothsayer in a swiftly changing world, let me attempt to deal with (1) the scientific, (2) the economic and (3) the educational future of medicine in the light of contemporaneous conditions.

THE SCIENTIFIC FUTURE

It seems reasonably safe to write that there will be an ever increasing dependence on the ancillary sciences of medicine—more and more will the physicist, the physiologist or the biologic or physical chemist play his part in elucidating the mechanism of abnormal syndromes and symptoms or in discovering the cure of disease. It is through the assistance and the cooperation of scientists in these fields that the why and wherefore of disease will become known, or it is through the mediation of the medical man trained in these special branches of science that new facts and fresh information will accrue to the science of medicine. The chemist, the research and practicing immunologist and occasionally the clinician will develop new chemical compounds, new specific serums and new operative procedures which will cure or ameliorate disease to an extent undreamed of at the present time. To the bacteriologist and to the sanitarian will fall the lot of preventing infectious diseases before their inception.

The mechanization of medicine grows apace. Less and less attention is being paid to the study of the patient by the unaided senses and more and more are instruments and machines being called on to make the diagnosis or to follow the course of disease. From the initial blood count to the final elaborate instrumental set-up in the constant temperature, air conditioned room, the patient, for example, with peripheral vascular disease, will be studied also entirely by the physical measures.

In the near future specifics will be obtainable for many if not all diseases, which will be diagnosed by bacteriologic, pathologic, chemical or physical means. The implications of the character of practice of medicine in this future era are obvious.

THE ECONOMIC FUTURE

In any discussion of the economic future of medical practice, two great trends must be noted. The first has to do with the ever growing socialization of the nation as a whole. There is now, and it will undoubtedly be greater in the future, a leveling out process whereby the large incomes are being restricted by taxation. Applied to the medical profession, this means that the large incomes of the occasional successful consultant or operator will approach more closely the level of the average professional income. The benefits accruing to the medical profession from such a change lie in the fact not that large incomes are to be deprecated or disdained but that certain questionable features in obtaining large incomes will be deleted, and no longer will the sole aim of many physicians be the accruing of a modest fortune. The second trend has to do with the socialization of medicine as a whole. This is an ever menacing terror to many physicians, but I venture to predict that if it comes about that medicine is completely regimented and totally under bureaucratic control, the care of the patient will be adequate, the life of the doctor will be interesting and happy, his income will be sufficient for his needs, and opportunity will not be lacking for the ambitious to advance. To me, and to most doctors, the idea of a future socialized medicine is a step backward. We look on it with abhorrence. We do not believe that it will help the patient and we feel confident that it will destroy professional initiative and self reliance, but most of us know in our hearts that, while methods may change, human nature is usually the same from generation to generation. The will and ability to enjoy life are inherent in the individual. He will get pleasure, profit and satisfaction out of doing a job well whether under the egis of an official or under his own personal supervision.

THE EDUCATIONAL FUTURE

I have speculated on the future of medicine in general and have hinted about the rather nebulous chimera of the distant future. Now I will present some ideas dealing specifically with internal medicine and present some thoughts concerning the immediate future of this specialty. Necessarily it will be impossible to do more than touch lightly on a few phases of the education of the medical undergraduate and graduate student in his relation to that which is to come.

As a result of the recent survey of the medical schools under the joint auspices of the Council on Medical Education and Hospitals of the American Medical Association, the Federation of State Medical Boards of the United States, and the Association of American Medical Colleges, there has been a reduction of 11 per cent in two years in the number of medical students matriculating at the various institutions teaching medicine. This result has been obtained by a strict limitation of the number of entering students to those for whom the laboratory and clinical facilities of the school were sufficient for the efficient training of the prospective physician. It is to be anticipated that the young physicians, selected from a large group of candidates for their scholastic ability, their personality and their hereditary and moral standards, will be an outstanding group. To these picked men may safely be assigned the future of medicine. That they represent a selected group which has passed the rigid requirements of medical instruction will enhance the solidarity of the profession and by their accomplishments encourage a friendly, but competitive, spirit of doing better work than the other man.

Within the past year a board has been set up which has to do with the certification of physicians qualified to practice the specialty of internal medicine. This board, as do the eleven other special boards, functions directly under the standards set up by the Council on Medical Education and Hospitals. A man who is certified by these boards as being competent in his special realm of medicine has had a full and complete training the adequacy of which is investigated by examination. Thus, in the near future, self-styled and imperfectly trained specialists who are their own judges of the extent and amount of knowledge they may have in a given branch of medicine will be eliminated. The public will be protected by certification if nothing else is obtained by this step. I have little sympathy for those who object to the principles and to the procedure, of certifying of specialists. Surely their good sense must tell them that this is a reform, a step in advance, which will do away with incomplete and deficient service to the public, which is in no position to acquaint itself with the merits or demerits of him it calls on to save an eye, to remove a tumor or to diagnose an early tuberculous infection. Every advance in medicine has been fought by a certain misguided few, from those in recent years who have objected to certification boards to those who opposed the reformation of medical education thirty years ago. Perhaps one reason that medical practice is as free as it is from governmental interference in this country at the present day is that the medical profession itself has been the first to see its weaknesses and the first to initiate self-corrective procedures.

A real problem presents itself in how best now to train the future specialists in internal medicine and how best to make use of existing facilities. Internal medicine is a broad field and knowledge of its finer niceties of diagnosis and treatment cannot be obtained in a day. It would seem advisable for medical schools to enlarge their horizon and to set up some mechanism whereby a man may secure graduate training in clinic and laboratory. This could be done by increasing materially the number of so-called fellowships in the various departments of the school. The fellow in clinical medicine should be paid a small, livable salary and in return for this and for the opportunity to learn he should be expected to do a certain minimal amount of routine teaching and class work. There are other opportunities for training. The larger hospitals could, as many do, readily establish advanced residencies where, under the supervision of a well trained staff, satisfactory training could be obtained in special branches. The release of members of the staff from routine by the advanced residents would enable the older men to give time to aiding and helping in the instruction of the younger. Still a third method suggests itself, the preceptorship. Many a man now in middle life who has had the opportunity of working under and with a good doctor realizes that much of what he knows has been obtained from his superior. It is suggested that many a mature clinician could take under his wing for a few years the budding clinician and in return for a small salary, for guidance in reading and for instruction in the practical application of theoretical information, the neophyte would relieve him of much routine and hackneyed detail. By one of these three methods of teaching it is believed that the qualified internist of the future will evolve.

SUMMARY

I have suggested how medicine of the future will develop. Scientifically it will undoubtedly progress. Economically and socially the future is less clear, but

it can be safely assumed that the delights of accomplishment and the fascination of the problems of medicine will ensure happiness to its practitioners. Educationally the future is bright. Undoubtedly many from a well trained group of men will take advantage of the facilities now existing and those to be established to qualify themselves as experts in limited fields of practice.

1430 Tulane Avenue

LATENT GONORRHEA AS A CAUSE OF ACUTE POLYARTICULAR ARTHRITIS

WESLEY W. SPINK, M.D.
AND
CHESTER S. KEEFER, M.D.
BOSTON

It is generally accepted, though specific data in medical literature are lacking, that gonococcic infections may remain dormant for years, and then, without history of reinfection, all the signs and symptoms of an acute gonorrhea may appear. Fraser and Dye¹ recently called attention to this in a report on a patient who had had a gonorrheal urethritis at the age of 20. Fifty years later, following a prostatectomy, there was an acute exacerbation of the gonorrheal urethritis.

It appears to be little known that latent gonococcic infections may have exacerbations with or without evidence of local genital lesions. Gonococcic arthritis is one of the most common of these infections. During the past three years we have studied seventy individuals with acute gonococcic arthritis. Of considerable interest were the observations on thirteen of these patients, who had a sudden onset of acute, polyarticular arthritis without symptomatic evidence of localized gonococcic infections of the genito-urinary tract. In several the arthritis was preceded by an acute upper respiratory infection, so that they were at first considered to have acute rheumatic fever. Four of these thirteen patients were female patients who developed acute gonococcic arthritis during pregnancy. At this time we present observations on these thirteen patients in order to emphasize the following: (1) the importance of latent gonococcic infections as a cause of acute arthritis, (2) a discussion of possible factors that may precipitate acute attacks of gonococcic arthritis, (3) diagnostic aids for distinguishing acute gonococcic arthritis from other types of polyarthritis, especially acute rheumatic fever.

It is well known that women may have an acute gonococcic infection of the genito-urinary tract with few or no symptoms. Ten of the thirteen patients were women who were ignorant of any gonococcic infection before entrance to the hospital. The cause of their arthritis was in doubt until it was found that each was harboring the gonococcus either in the joints, tendon sheaths or the genito-urinary tract. In two of the three men studied, we were unsuccessful in demonstrating any gonococcic infection of the genital tract. One stated that he had a gonococcic urethritis eighteen months before entry and the other five years before. The

third man did not admit of ever having a urethral discharge, but after two vigorous prostatic massages the gonococcus was obtained. Gonococci were isolated in pure culture from the joints of the three men and from five of the eight women. Gonococcus complement fixation tests done on the blood or synovial fluid of twelve of the thirteen patients were positive in nine and negative in three.² The significance of this will be discussed presently.

When a young person and, as Ferris and Myers³ have recently shown, elderly patients have a sudden onset of acute polyarticular arthritis, acute rheumatic fever must be seriously considered. This is especially true if the pains in the joints have been preceded by a sore throat or tonsillitis. Seven of the thirteen patients studied were at first thought to have had acute rheumatic fever because their arthritis was preceded by a severe, acute upper respiratory infection. There appeared to be no symptomatic evidence of a localized gonococcic infection.

In the following case a severe attack of tonsillitis was followed by an acute polyarthritis. Although the patient's hymen was intact, it was later proved that she had an acute gonococcic urethritis without symptoms, and cultures from the pus aspirated from a joint yielded gonococci.

CASE 1.—M. C., a woman aged 21, single, Italian, complained of a severe sore throat with chills and fever ten days before entry to the hospital. Two days later she had pain and swelling of both knees and swelling of the dorsum of the right hand, index finger and right shoulder. She later developed difficulty in swallowing because of enlarged cervical glands. There was no previous history of arthritis or genito-urinary symptoms. Physical examination showed her to be well developed and nourished, and in acute pain. Her throat was injected and the tonsils were enlarged and cryptic. The cervical nodes were enlarged and tender to palpation. The heart, lungs and abdomen were within normal limits. The right knee joint was swollen, red and tender, with evidence of fluid present in the joint space. There was pain on motion of the right hand and right shoulder. There was no vaginal discharge, and the hymen was intact. Laboratory data revealed occasional red and white blood cells in the urinary sediment. The blood showed a slight hypochromic anemia and leukocytosis. The Kahn test on the blood serum was negative for syphilis, and two gonococcus complement fixation tests were negative.

Because the polyarthritis was preceded by a severe sore throat, the diagnosis of acute rheumatic fever was entertained. The pains in the joints did not respond well to salicylates. The right knee, which continued to show evidence of fluid, was aspirated and a pure culture of gonococci was obtained. Close questioning of the patient revealed a story of incomplete coitus several months before. Gonococci were obtained in pure culture from the urethra. The knee joint was opened and irrigated, and, after orthopedic measures, she made an excellent recovery.

The foregoing illustrates two points of value in the diagnosis and treatment of acute arthritis. First, when a patient with acute polyarthritis fails to show improvement with large doses of salicylates, the joint symptoms may not be a manifestation of acute rheumatic fever. Second, it is of great value to aspirate and culture the fluid from any joint with a demonstrable effusion to aid further in the diagnosis.

The necessity of differentiating, early in the disease, acute rheumatic fever from gonococcic arthritis from the point of view of treatment is emphasized by the

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School.

¹ Fraser, C. K., and Dye, W. J. P. Acute Exacerbation of Latent Gonorrheal Urethritis After Fifty Years Following Prostatectomy. *J. A. M. A.* 105: 269 (July 27) 1935.

² The tests were done by the Wassermann Laboratory of the Department of Health of the Commonwealth of Massachusetts. Dr. William A. Hinton, director.

³ Ferris, E. B. Jr., and Myers, W. K. Initial Attacks of Rheumatic Fever in Patients Over Sixty Years of Age. *Arch. Int. Med.* 55: 809 (May) 1935.

following case This patient was also unaware of any localized gonococcal infection and developed polyarthritis following an upper respiratory infection She was treated for three weeks for acute rheumatic fever, and at that time aspiration and culture of fluid from a knee joint revealed gonococci The inflammatory process had continued for so long that there was considerable destruction of the tissues of the knee joint, and permanent ankylosis resulted in spite of operative measures

CASE 2—D M, a white woman aged 25, a Canadian, developed an acute upper respiratory infection three days before entry The evening of onset she noted twinges of pain in her left knee, both ankles, elbows, wrists and all the fingers She felt feverish and thirty-six hours later observed several widely separated, red "bumps" on her trunk and extremities The day before entry she noted redness and swelling of the left knee and of one finger on both hands She denied venereal infection by name and symptom and had no leukorrhea or genito-urinary symptoms

The patient was well developed and nourished and appeared acutely ill She complained of pains in the joints Positive signs were limited to the joints, which included a swollen, red and hot left knee with evidence of an effusion into the joint space There was swelling and pain of the second proximal joint of the left hand and of the second metacarpophalangeal joint of the right hand There was no vaginal discharge, tenderness or masses in the vaults Laboratory examination revealed an occasional white blood cell in the urine The hemoglobin and erythrocyte count were within normal limits There was moderate leukocytosis There was a negative Kahn test for syphilis

She responded poorly to salicylates Because of continued joint pains and fever, a gonococcus complement fixation test was done on her blood and reported as positive A second test was positive, and a cervical smear revealed gram-negative intracellular diplococci At the end of the third week in the hospital the left knee was aspirated and a pure growth of gonococci obtained from the fluid Her knee was opened and the joint cavity washed out She had a prolonged period of convalescence, and on discharge from the hospital there was only 10 degrees motion of the knee This was due in large part to an ankylosis of the patella to the femur

There were two male patients who had an acute upper respiratory infection followed by arthritis, and they were suspected of having acute rheumatic fever Both had had a gonococcal urethritis in the past, but on entry to the hospital there was no urethral discharge even after vigorous massage In both, an early diagnosis of gonococcal arthritis was made by aspiration and culture of gonococci from the synovial fluid The gonococcus complement fixation tests of the blood were negative in both The following is the case history of one of these patients

CASE 3—I R, a man aged 56, Jewish, became thoroughly chilled and wet six days before entry to the hospital The following day he was feverish, developed a cough, and remained in bed for three days Two days before entry, he again exposed himself to severe weather and became chilled Following this he felt feverish and perspired profusely The day before entry he developed excruciating pain in the right knee and both feet At the same time he noted a purplish rash on both legs and thighs He stated that he had rheumatism twenty years previously with all joints involved, which lasted several months He had had a gonococcal urethritis eighteen months previously but had had no discharge or symptoms since then

The patient was well developed and nourished and he appeared acutely ill There was present on the skin overlying the trunk, extremities and face a dull red, macular eruption not fading on pressure A few lesions appeared petechial In some areas the lesions were small elevated papules The right knee was painful to motion, with evidence of an effusion into the joint There was pain on pressure over the plantar surfaces of both

feet The prostate was of normal size and consistency and not tender The urine was normal The blood showed a slight hypochromic anemia with leukocytosis A blood culture showed no growth Both a Kahn test and a gonococcus complement fixation test on the blood were negative

On the day following admission, fluid was aspirated from the right knee, and gonococci were obtained in pure culture. The knee was opened and washed An uneventful convalescence followed, with complete recovery of function of the right knee.

In the foregoing cases upper respiratory infections preceded an attack of gonococcal arthritis, while in the following case the antecedent infection was of a different nature This patient had a cellulitis of the foot, which was followed by an acute polyarthritis and treated as acute rheumatic fever until a pure culture of gonococci was isolated from a tendon sheath

CASE 4—P F, a woman aged 28, single, was in good health until two weeks before entry, when she developed a blister on the right heel because of an ill fitting shoe This was followed by swelling, redness and pain of the entire right foot, and she was treated by her physician for cellulitis Three days after the onset of this swelling she developed pain and swelling of the left wrist, and a week later there was a similar involvement of the right wrist Just before entry, the fingers of both hands became stiff and painful

The patient was well developed and slightly obese She complained of pain in both wrists The nose and throat were reddened with a slight mucopurulent discharge The heart and lungs were within normal limits There was pitting edema, heat and redness over the dorsum of the right hand The ulnar aspect of the left wrist was very tender and slightly red The right heel showed a healing ulceration with evidence of a previous swelling Vaginal examination showed no discharge or tenderness Laboratory data included six examinations of the urine, and all of them were within normal limits The blood hemoglobin and erythrocyte count were normal There was a slight leukocytosis The Kahn test of the blood was negative

At first it was thought that the patient had an atypical attack of acute rheumatic fever following a streptococcal infection of the foot Five days after entry, a small fluctuant area over the back of the right wrist was observed This was aspirated with a fine needle, and a pure culture of gram negative diplococci was obtained which proved to be gonococci by agglutination tests A gonococcus complement fixation test of the blood was negative at first but positive on two later examinations An examination of material from the uterine cervix showed gram-negative intracellular diplococci She recovered from the arthritis completely following simple orthopedic measures

There were four women who had gonococcal arthritis as a complication of pregnancy It is recognized by obstetricians that pregnancy may cause latent pathologic processes, including infections, to increase in severity Gonococcal infections appear to be no exception As far as could be determined, there was no evidence that these four patients had acute symptoms due to a localized gonococcal infection prior to their entry to the hospital Three of the patients were from three to four months pregnant when they developed a severe polyarthritis The gonococcus was isolated in pure culture from the uterine cervix of each of the three patients and from the hip joint of one One patient died of bronchopneumonia following an operation on a joint The fourth patient presented considerable interest because she developed a gonococcal septicemia with a septic polyarthritis following a self-induced abortion She had no knowledge of symptoms referable to a previous localized gonococcal infection Her clinical history was as follows

CASE 5—H D, a woman aged 28, married a housewife, was the mother of five healthy children She entered the hospital because of uterine hemorrhage following a self induced abor-

tion. A dilation and curettage was done and after two weeks she left the hospital. Two days after discharge from the hospital she developed chills, fever, and pain in the right wrist. At the same time she suffered from low abdominal pain and had a profuse vaginal discharge. Two weeks later she observed a skin rash involving her body, face and extremities. Three weeks after the onset of her illness she entered the hospital.

The patient was emaciated and appeared chronically ill. On the skin of the face, hands, legs and feet there were varying sized maculopapular and vesicular lesions. She had bilateral low abdominal tenderness on palpation. Both wrist joints and the fifth finger of the left hand were swollen and painful on motion. The uterine cervix was enlarged and boggy, and there was tenderness in both vaults. Laboratory data showed the urinary sediment consistently loaded with white blood cells. She had a marked hypochromic anemia and leukocytosis. The Kahn test on the blood was negative. The gonococcus complement fixation test was negative on admission, doubtful the third week after entry, and positive the fifth week. The cervical smear revealed gram-negative intracellular diplococci. A gram-negative diplococcus was isolated from the blood stream on three occasions, which proved to be gonococci by agglutination and fermentation tests.

When it was learned that the blood culture showed gram-negative diplococci, a fine needle was inserted into the right wrist joint and a drop of purulent material aspirated. Cultures of this yielded gonococci. For the first ten days she had chills and fever every other day. Cultures of material from the skin lesions were taken and stained but no organisms were seen. In the fourth week she showed marked improvement following a blood transfusion. On discharge from the hospital, she had an ankylosis of the right wrist joint.

The following case presented most difficult therapeutic and diagnostic problems. The patient entered the hospital in diabetic coma and developed signs of bronchopneumonia. This was followed by a sudden onset of acute polyarthritis with a high fever. The joint symptoms were not alleviated by large doses of salicylates. After several weeks had elapsed, a gonococcus complement fixation test was done and reported as positive. Two months after entry, after repeated attempts, a culture of gonococcus was obtained from a joint.

CASE 6—K W, a Negro aged 17, single, entered the hospital in coma of eighteen hours' duration. One month before, he was said to have noted loss of weight, polyuria and polydipsia. He was markedly undernourished and dehydrated. His throat and mouth were dry. The lungs, heart and abdomen were within normal limits. The reflexes were sluggish. Laboratory data revealed a brick red test for sugar in the urine. The red blood count and hemoglobin were normal. There was moderate leukocytosis. The blood sugar was 494 mg per hundred cubic centimeters. The carbon dioxide combining power was 9.8 volumes per cent, and the blood nonprotein nitrogen was 60 mg per hundred cubic centimeters.

He was given large amounts of fluid and insulin and in the course of forty-eight hours gradually recovered consciousness. At the end of the first week he had fever and signs of consolidation at both lung bases, confirmed by x-ray examination. The signs in the lungs cleared, but he began to complain of joint pains and he continued to have fever. He was suspected of having acute rheumatic fever, which was supported by slight electrocardiographic changes. The joint pains were not relieved by salicylates, and a gonococcus complement fixation test done shortly after was reported as positive. Two subsequent tests were also positive. There was no evidence of an acute urethritis, and he had no knowledge of any previous urethral discharge. A prostatic massage yielded a few drops of purulent material, which contained gram negative intracellular diplococci. Four and one-half weeks after entry to the hospital, his temperature was spiking at 102 to 103 F. Coincident with the second prostatic massage, his temperature dropped to a normal level and remained there. The left subacromial bursa was aspirated and purulent fluid obtained but the culture was sterile. Eight weeks after entry, the right elbow was opened surgically

and purulent fluid was obtained. Culture of this showed gram-negative diplococci, proved to be gonococci by agglutination with immune serum. Following this, he recovered rapidly with his diabetes controlled by diet and insulin. There was slight limitation of motion of the right elbow on discharge from the hospital.

The next case illustrates that acute gonococcal arthritis may appear following a pelvic operation in a patient in whom it was not possible to obtain a history of a gonococcal infection, and no organism could be isolated from the pelvic organs.

CASE 7—C C, a white woman aged 54, married, a housewife, complained of the gradual development of a "dragging down sensation" in the pelvis, with a presentation of the cervix at the introitus. Coincident with this there appeared a yellowish, "scalding," vaginal discharge. She had moderate dysuria and frequency. Her menstrual periods had been regular until one year before entry, when they ceased. There was no evidence in her past history indicating the presence of a gonococcal infection. Her husband was living and well, and she had three healthy children.

The patient was well developed and nourished. She appeared much older than her stated age. Several teeth were missing, only carious stumps remaining. Her lungs were clear. The heart was within normal limits. Blood pressure was 150 mm of mercury systolic and 90 diastolic. The abdomen was slightly distended. Rectal examination revealed a uterus of normal size and movable, in second degree retroversion. On straining, the cervix presented itself at the introitus. The mucous membrane was intensely injected and there was a profuse discharge. There was thickening of the anterior vaginal wall. The skin of the adjacent thighs was red and thickened. The cervix was lacerated and hypertrophied. Laboratory data showed that the urinary sediment contained numerous white blood cells. A Hinton test of the blood serum was negative for syphilis.

Three days after entry a complete plastic operation was done, which included repair of the cervix, an anterior colporrhaphy, a posterior perineorrhaphy, and an Olshausen suspension of the uterus. When the peritoneal cavity was opened, the tubes appeared normal and the ovaries small and sclerotic. The pathologist's report on the cervix was "cervical erosion, chronic endocervicitis."

The patient had an uneventful postoperative convalescence and was allowed out of bed on the twelfth day after operation. Because of a tachycardia without symptoms, she was put back to bed. Two days later a tender mass appeared in the right groin. She had a temperature of 100 to 101 F. This was considered to be due to a thrombophlebitis of the right external saphenous vein. Four days later, or on the eighteenth day after operation, she had pain and slight swelling of the left knee, which increased in severity within the next few days. Three days after the onset, an x-ray examination of the knee was reported as giving results within normal limits. At this time, fluid was aspirated from the left knee joint. Culture of this fluid yielded a pure growth of gram-negative diplococci, which proved to be gonococci by fermentation and agglutination tests. At this time she also noted pain on motion of the fingers of the left hand and of the left wrist. A cervical culture at this time showed no gonococci. During the next week she continued to have a febrile course. The swelling and pain of the left knee persisted with complete limitation of motion. Fluid was aspirated from the joint seven days after the initial aspiration. Because the consistency of the fluid was much thicker than previously, and because of the continued presence of gonococci, an open drainage and lavage of the knee joint was done. Following this the wound was sutured tightly and skin traction put on the leg. Following the operation, the pain and swelling of the knee subsided and forty-three days later the patient was discharged from the hospital with no limitation of motion of the left knee.

In brief, then, a woman who gave no history of a gonococcal infection in the past was operated on for prolapsed uterus. Eighteen days later, acute arthritis of the left knee joint appeared which was proved to be due to gonococcal infection. Complete recovery followed adequate treatment.

This case illustrates that gonococcal arthritis may appear with no demonstrable focus in the genito-urinary tract, and it further emphasizes the importance of the examination of the synovial fluid in all cases of arthritis having an effusion into the joint spaces

COMMENT

These cases illustrate the well known fact that gonococcal arthritis may be present without any symptoms referable to the genito-urinary tract. Of still greater significance are the cases in which there are no symptoms or signs of a local lesion in the genito-urinary tract but gonococci can be isolated from the synovial fluid. It is a matter of common experience that women may develop acute gonococcal polyarthritis without any symptoms or signs referable to the genito-urinary tract, but the fact that the original focus of infection may disappear and arthritis arise later is not generally appreciated. We emphasize this point in order to encourage the bacteriologic examination of synovial fluid.

We should also like to call attention to the observation that the appearance of arthritis may be preceded by an acute upper respiratory infection or an acute infection elsewhere, or it may come on during pregnancy. In eight of the thirteen cases the arthritis was preceded by an acute upper respiratory infection, in four it appeared during pregnancy, in one it followed an acute cellulitis of the foot, and in one it developed soon after a pelvic operation.

In the diagnosis of gonococcal arthritis we have found the following examinations of most importance: (1) examination of the synovial fluid for micro-organisms, (2) the gonococcus complement fixation test on the blood, (3) the isolation of organisms from possible foci of entry, (4) the course of the disease.

In our experience with forty-two samples of synovial fluid from patients with gonococcal arthritis the culture was positive in sixteen. Since synovial fluid does not contain organisms in all cases, it is necessary to rely on other examinations, such as the patient's history, clinical course, the finding of gonococcal infection elsewhere, and the gonococcus complement fixation test. This test was done on the synovial fluid of thirty-five patients. It was positive in twenty-one cases, negative in thirteen and doubtful in one.

It is of some interest that in six synovial fluids with organisms the gonococcus complement fixation test was negative. The reason for the sterile synovial fluid in some of these cases is the presence of a high antibody titer. This aspect of the synovial fluid examination will be discussed in detail elsewhere.

In fifty-four cases of gonococcal arthritis the gonococcus complement fixation test was positive on the blood in forty-seven, negative in five and doubtful in two. This test may show a positive reaction as early as the first week of the disease and remain positive as long as two years after all symptoms have subsided. In suspected cases of gonococcal arthritis it may be necessary to do repeated gonococcus complement fixation tests frequently as a positive reaction may not be obtained until several weeks after the onset of symptoms.

SUMMARY AND CONCLUSIONS

Observations on thirteen patients with acute polyarticular arthritis of gonococcal origin emphasize the importance of latent gonococcal infections as a cause of acute arthritis. In seven of these cases, joint symptoms were preceded by an acute upper respiratory infec-

tion so that acute rheumatic fever was suspected. There were several in the group without clinical or laboratory evidence of a localized genito-urinary gonococcal infection. Various methods of diagnosis were employed and have been outlined with particular reference to the value of a bacteriologic examination of synovial fluid and to the gonococcus complement-fixation test.

Picrotoxin in the Treatment of Barbiturate Poisoning

REPORT OF CASE

EDWARD M. KLINE, M.D.
Instructor, Department of Internal Medicine

EDWARD BIGG, M.D.

H. A. K. WHITNEY, Ph.C.
Chief Pharmacist, University Hospital

ANN ARBOR, MICH.

Picrotoxin was discovered by Boulay in 1812¹ but it was not until 1847 that a rational use for it was suggested by Tschudi,² when he expressed the opinion that it might be a suitable antagonist to morphine. In 1875 J. Crichton Browne³ published a series of papers in the *British Medical Journal* dealing exhaustively with the pharmacology of the drug and in particular suggested its use in the treatment of chloral hydrate poisoning. A review of the subsequent literature gives little evidence that picrotoxin enjoyed any popularity in these connections. However, in recent years it has once more received attention following the proposal of Maloney, Fitch and Tatum⁴ that the drug be used as an antidote in barbiturate poisoning.

RECENT LITERATURE

Having demonstrated in their first paper⁴ that picrotoxin was of value in antidoting poisoning by the shorter acting barbiturates, Maloney and Tatum⁵ in a second report dealt with those of the longer acting type. The conclusions in the publications did not differ materially. These were, in brief, that (1) picrotoxin shortened the recovery time following the administration of sublethal doses of these compounds, (2) cures were effected in the case of lethal doses within certain limits, and (3) beyond these limits the life of the animals was prolonged.

Comparison of the effectiveness of picrotoxin and other analeptics as antidotes in acute experimental barbiturate poisoning have produced encouraging and consistent results. Maloney, in evaluating the efficiency of picrotoxin and strychnine⁶ and of picrotoxin, strychnine and cocaine⁷ as antidotes in barbiturate poisoning in the rabbit found a higher percentage of recoveries following the use of picrotoxin than for

either of the others tested. Eleven typical members of the barbiturate group were used in both studies.

More recently Barlow⁸ reported on the use of a somewhat larger series of analeptics as antidotes to sublethal and lethal dosages of pentobarbital, chloral hydrate and tribromethanol. He summarizes his results as follows:

The order of practical usefulness of the several therapeutic measures, judged by the degree of improvement in respiration, circulation and reflex excitability, degree of shortening of the usual stages of recovery and the margin of safety of effective dosages of each agent from high to low is as follows: picrotoxin, metrazol, ephedrine, artificial respiration, "coramine," "icoral," strychnine, and caffeine sodio-benzoate.

Koppanyi⁹ and his associates found that the action of picrotoxin in antidoting barbiturate poisoning is both cortical and medullary. When minimal anesthetic doses of the barbiturate have been given, this cortical awaken-

ing the administration of picrotoxin is a slow but gradual rise in the blood pressure and respiratory rate to normal levels.

CLINICAL DATA

While experimental evidence in favor of the use of picrotoxin in barbiturate poisoning has rapidly accumulated (no attempt has been made to mention all experimental literature) there has been a conspicuous absence of detailed papers dealing with its clinical application. Arnett's¹⁰ case is difficult of interpretation since the patient, a 3 year old child, was not known to have taken a fatal dose and the picrotoxin was supplemented by other therapeutic measures. Koppanyi^{9b} in his presentation of clinical material describes two cases of severe poisoning treated with picrotoxin alone. Recovery was prompt in one instance and was well established in the other, when the patient succumbed to bronchopneumonia.

Details of Clinical Course

Time	Temperature (Rectal)	Pulse	Respirations	Blood Pressure	Medication	Clinical Notes
3/10/37 12 30 a m	97.5	70	20	80/70	Gastric lavage with sodium bicarbonate mucus aspirated from throat	Patient completely flaccid, responds to extreme pain stimuli, pupils constricted, reflexes absent and skin cold, laboratory examinations negative
1 20 a m	98.0	70	20	80/70	First subcutaneous dose of picrotoxin* 0.003 Gm. this represents mode of administration and quantity of all subsequent doses	
3 40 a m	98.2	80	20	92/70	A total of five doses of picrotoxin has been given, approximate interval between doses 30 minutes. Intravenous 5% dextrose begun	Condition unchanged
5 10 a m	98.6	82			A total of ten doses of picrotoxin has been given, approximate interval between doses (from fifth to tenth) 18 minutes	Generalized muscular twitchings with spasticity and resistance to passive motion. Slight stimulus causes clonic convulsions, all reflexes hyperactive, this state persisted for 15 minutes
4 30 p m	101.5	105	24	120/70	A total of twenty three doses of picrotoxin has been given, approximate interval between doses (from tenth to twenty third) 30 minutes. final dose total amount given 0.069 Gm.	Patient moves about spontaneously, general condition improved, reflexes continue to be slightly hyperactive
3/11/37 6 00 p m	102.8	115	30	120/80	Completion of intravenous dextrose, total amount given 7.260 cc	Bilateral bronchopneumonia demonstrated by roentgenogram W B C 13500
3/12/37 9 00 p m	102.0	100	20	110/70		Completely oriented, muscles tender to palpation, marked improvement throughout day
3/12/37 9 00 a m	99.0	76	20	120/75		Patient feels fine and has no complaints, physical examination entirely negative W B C 7400

* Ampoules Picrotoxin Lilly, Eli Lilly & Co. Each 1 cc ampule contains 0.003 Gm of picrotoxin.

ing effect is seen frequently in animals and in man within a few minutes after the intravenous administration of the antidote. The concentration of barbiturate in animals so awakened in most instances does not differ from that in depressed controls. The implication is, therefore, that picrotoxin does not hasten the destruction of barbiturate but rather that the two are physiologic antagonists. It is the impression of Koppanyi and his associates that the more normal physiologic state of the awakened animals (and presumably man) enables them to destroy larger amounts of barbiturate. In addition to these cortical actions there is a direct stimulatory effect on the respiratory and circulatory centers. The typical response follow-

The following protocol is presented in some detail as an example of the dose employed, the frequency of administration and the response obtained.

REPORT OF CASE

History—J. B., college student, aged 20, had been in excellent health until March 8, 1937, when, following an emotional upset, he became depressed. The following day he conducted himself in a normal manner until 9 30 p m, when he was found in a comatose condition. He could not be aroused, but a suicide note and an empty amylal bottle nearby suggested the diagnosis. A physician was summoned, who gave him one subcutaneous injection of strychnine 1 mg, and sent him to the University Hospital, where he was admitted at 12 30 a m.

Later we learned from the patient, and from the druggist who made the sale, that this bottle had contained thirty amylal tablets of 0.1 Gm (1½ grains) each. The total number had been ingested and retained.

The past history was irrelevant. The patient's mother is an inmate of a state psychopathic hospital suffering from manic-depressive psychosis.

portions. Each portion was tested with Millon's reagent for the presence of free phenol and if free phenol was found only in the first 20 cc of the distillate, it was termed one plus, if in the first and second, two plus, if in the first, second and third, three plus, and in all four, four plus. The same procedure was followed after each patient was given an intravenous injection of 20 cc of guaiacol solution.

Table 1 shows definitely that, when a solution containing free guaiacol is given intravenously to patients with lung abscesses, their sputums for from forty-eight to seventy-two hours after the injection contain a substance which gives a positive reaction with Millon's reagent. In view of the fact that no phenol bodies were present in the sputums of these patients for four consecutive days prior to the intravenous administration

administration of the guaiacol solution, the drainage from the abscess cavity contained a volatile phenol which gave a positive reaction with Millon's reagent. It is evident, then, that when guaiacol is injected intravenously it is excreted through the lungs of patients with lung abscesses as a volatile phenol body.

TREATMENT

The following routine was adopted for the treatment of patients with acute or chronic lung abscesses:

- 1 Bed rest if the rectal temperature was above 99.8 F
- 2 Twenty-four hour collection of sputum
- 3 Temperature taken every four hours
- 4 X-ray films of chest, in postero-anterior, lateral and oblique positions, repeated every three to four weeks
- 5 Examination of teeth and careful mouth hygiene and extraction of decayed teeth if necessary
- 6 Bronchoscopy soon after admission
- 7 No tobacco or alcoholic drinks
- 8 High caloric diet
- 9 Intravenous injection of guaiacol every third or fourth day. All patients were given the solution until the amount of the sputum was reduced, its foul odor disappeared and the general condition of the patient improved.
- 10 On discharge the patient was sent to a convalescent home and not permitted to resume work until the roentgenograms revealed complete healing.

The summarized results of twenty treated cases are shown in table 3. A short summary of each case is presented, with roentgenograms, temperature chart and daily sputum output of three.

REPORT OF CASES

CASE 1—J. B., a white man, aged 42, was admitted Dec 6, 1930, to the alcoholic ward of Bellevue Hospital. He had been intoxicated for two weeks. He was found to have a consolidation of the right upper lobe and a temperature ranging from 102 to 104. After two weeks he was transferred to the medical service as his lung condition showed no improvement. He began to expectorate from 4 to 8 ounces (120 to 240 cc) of foul purulent sputum daily. A roentgenogram revealed a large cavity with a fluid level in the right upper lobe with a large area of infiltration surrounding it.

The sputum was negative for acid fast bacilli. The blood Wassermann reaction was negative.

He was given twelve injections of guaiacol and sodium iodide solution within a period of nine weeks. The sputum lost its foul odor after three weeks and the temperature returned to normal. The amount of sputum diminished until, when discharged, Feb 27, 1931, the output was nil.

CASE 2—L. S., a white man, aged 35, was admitted June 30, 1930, with a history of sour gaseous eructations followed by a cough productive of foul purulent sputum of one month's duration. These symptoms appeared after a bout of drunkenness. Previous to this he had been well.

He continued to have a septic temperature, ranging from 99 to 103. The sputum output was from 5 to 10 ounces (150 to 300 cc). He was treated with bed rest and postural drainage and on discharge, July 30, he was still raising from 4 to 6 ounces (120 to 180 cc) of foul material. He went to another hospital where he remained until Sept 1, 1930.

He was readmitted Jan 25, 1931, with a history that he was well until five weeks previously when he "caught cold." Since

Fig. 2 (case 6)—The clinical course during both admissions. The lower solid area shows the daily twenty-four hour sputum output in ounces. The individual solid blocks indicate the days guaiacol was administered and above is shown the daily temperature fluctuations—maximum and minimum in each twenty-four hour period. The progress of the case is also shown by the roentgenograms which were taken reading from left to right July 20, 1931, after the patient had been in the hospital a week on general care; August 20, on the second admission; September 23, on discharge after treatment; and October 1935, four years after discharge from the hospital.

of guaiacol, it is reasonable to assume that the phenol body present in the sputum after the injection is guaiacol or a derivative of it.

While these experiments were being conducted, a patient with a putrid lung abscess was operated on in our surgical division (thoracotomy). It was deemed wise to examine chemically the drainage from the lung for the presence of volatile phenols. The drainage was collected for two consecutive days and the dressings and drainage distilled with steam. The distillate was collected in 20 cc portions as described previously and each portion tested with Millon's reagent. The patient was then given an intravenous injection of 20 cc of the guaiacol and iodide solution and the drainage and dressing for the next seventy-two hours collected and treated as before. The results are shown in table 2.

The drainage from the lung abscess cavity contained no volatile phenol bodies, but, following the intravenous

then he had been coughing and expectorating large amounts of foul sputum. His admission temperature was 102. The daily sputum output was from 15 to 20 ounces (450 to 600 cc) and was negative for acid fast bacilli. He was given an injection of 20 cc of guaiacol and iodide solution every third day. The temperature dropped, the sputum decreased in foulness and amount, until after the second month when the output was only 1 ounce (30 cc). Jan 30, 1931, the output was nil and the temperature had been normal for two months.

CASE 3—C Q, a white man, aged 23, a machinist, was admitted March 23, 1931, with a history that two years prior to this admission he had fractured two ribs in the left lower part of the chest. Three months after this subsided he developed pain in the left chest, with cough, fever and foul expectoration. He was treated with prolonged bed rest for six months. He was well until a week before, when he developed a chill and pain in the left side of the chest, with fever and cough productive of foul smelling sputum, which was negative for acid-fast bacilli. The blood Wassermann reaction was negative.

The roentgenograms showed a large area of consolidation involving the entire left lower lobe, with numerous areas of lessened density adjacent to the left lower border of the heart.

The temperature ranged from 102 to 104.6, with from 10 to 14 ounces (300 to 420 cc) daily sputum output.

After injections of guaiacol and iodide solution were given every third day, the temperature gradually dropped and the sputum diminished in odor and amount. On discharge, June 22, the x-ray films showed an area of fibrosis in the left lower lobe, the temperature was normal and there was no expectoration.

CASE 4—C M G, a white man, aged 47, a painter, was admitted April 8, 1931, with a history of a cold for a month with pain in the right lower part of the chest and a cough productive of foul sputum. He had been well until the onset of this cold.

The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. His temperature ranged from 101 to 103 and the sputum output was from 4 to 6 ounces (120 to 180 cc) daily. The roentgenogram showed an abscess of the right lower lobe. He was given an injection of guaiacol every third day, and on discharge, May 27, the sputum was nil and the temperature normal.

CASE 5—W S, a white man, aged 42, a clerk, was admitted April 10, 1931, with a history that he had been well up to six weeks before, when he had a chill but continued to work despite a high temperature. He later developed a cough and then had a hemoptysis, the sputum became profuse and foul.

The blood Wassermann reaction was negative. The sputum was negative for acid-fast bacilli.

The temperature rose to 103 and the sputum output was up to 8 ounces (240 cc) daily.

A roentgenogram showed an irregular patch of consolidation in the lower portion of the upper lobe of the right lung, with a cavity 2 inches in diameter.

He was given an injection of guaiacol every fourth day. The temperature dropped to normal and the sputum lost its foul odor and diminished in amount, until on discharge, May 6, the daily sputum output was nil and the temperature normal.

CASE 6—J J S, a white man, aged 59, a clerk, was admitted May 29, 1931, with a history of pain in the right lower part of the chest with productive cough the onset occurring three weeks previous to admission. The sputum was negative for acid fast bacilli. The blood Wassermann reaction was negative. The roentgenogram showed an area of infiltration extending out from the right root in all directions.

He remained on bed rest and postural drainage for fifty days with no improvement of his symptoms, the sputum output varying from 6 to 10 ounces (180 to 300 cc) daily. The patient went home unimproved, July 19.

He was readmitted Aug 24, 1931, emaciated and raising from 4 to 5 ounces (120 to 150 cc) of foul sputum. There was marked gingivitis. The sputum was negative for acid-fast bacilli. The roentgenograms showed infiltration about the right root extending into the lower lobe.

Intravenous injections of guaiacol and iodide were given every fifth day. The sputum lost its foul odor and became diminished in amount and the temperature fell to normal. On his discharge, September 23, the patient was greatly improved, he was symptom free, the sputum output was nil, and the x-ray film showed marked fibrosis around the root of the right lung. The patient weighed 137 pounds (62 Kg) on admission and on discharge 151½ pounds (69 Kg), a gain of 14½ pounds (6.5 Kg).

CASE 7—F L, a white man, aged 57, a waiter, was admitted July 10, 1931, with a history of having an alcoholic debauch.

Fig 3 (case 9)—The clinical course while under treatment in the hospital. The solid area on the bottom indicates the daily twenty four hour sputum output in ounces. Above is indicated the days medication (guaiacol) was given and the daily temperature fluctuations—minimum and maximum in each twenty four hour period. The roentgenograms reading from left to right were taken May 23 1932 shortly after admission, October 11 just prior to discharge from the hospital and May 5 1935 after one year follow up in our clinic.

eight weeks previously and shortly afterward developing a cough productive of a large amount of sputum and associated with pain in the left upper part of the chest. He was emaciated and his teeth and gums were in very poor condition.

The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. The roentgenogram showed a large abscess cavity in the left upper lobe with fluid level and a large area of infiltration about the root. The right lung showed evidence of infiltration of the root and upper lobe with abscess formation.

The patient was kept in bed and postural drainage was instituted for eighteen days but without improvement. Intravenous injection of guaiacol and iodide was begun and with subsidence of the temperature the patient improved markedly. The sputum remained profuse, although the foul odor disappeared. The patient refused to have his teeth and gums treated and began to smoke a great number of cigarettes daily.

Two months later he began having a septic temperature and the sputum increased in amount although it remained odorless. X-ray examination at this time showed the process in the left upper lobe to be clearing but the conditions in the right

upper lobe remained unchanged. Injections were continued until he was discharged, April 20, 1932, when the roentgenogram showed marked fibrosis in both upper lobes at the level of the first ribs. The temperature had been normal but the sputum continued profuse, about 4 ounces (120 cc) daily, although odorless.

The patient was sent home, returning May 21, 1932, for a check up and was finally discharged June 12, 1932. The temperature was flat, the sputum was not foul but continued to be fairly profuse, averaging from 4 to 5 ounces (120 to 150 cc) daily. X-ray examination showed fibrosis at the roots of both lungs and above the first rib, with several small areas of rarefaction bilaterally above the first rib.

He persistently refused to have his teeth treated and a number of them fell out. He continued to smoke and drink as heavily as previously. He died March 30, 1934, of type I pneumonia of the right lower lobe.

CASE 8—J C, a white man, aged 42, a laborer, was admitted because of cough, blood-streaked sputum and loss of weight since September 1930. He worked in a very dirty and smoky atmosphere. He had been treated at another hospital where bronchoscopy and x-ray examination had been done. A roent-

the grip. There was also pain in the left side of the chest, which was very severe at times. For the past few weeks he noticed that the sputum was sour.

The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. His temperature was septic and the sputum output was from 8 to 16 ounces (240 to 480 cc) daily. An x-ray film showed an area of infiltration over the root of the left lung, extending posteriorly to the heart.

He was put on bed rest and postural drainage for one month but showed no improvement. Intravenous injection of guaiacol and iodide was begun. The sputum output increased in amount but the foul odor disappeared. After showing a septic course for the next two months, the temperature fell to normal, the sputum output was reduced to 2 ounces (60 cc.) daily and with further treatment the sputum output was reduced to 0. On discharge, Sept 2, 1934, the x-ray film showed fibrosis about both roots and in October the x-ray picture was perfectly normal.

CASE 10—G D, a white man, aged 43, a janitor, was admitted June 7, 1932, with a history of shortness of breath and cough for the past year. In December 1931 he was ill for

Fig 4 (case 12)—The clinical course while in the hospital—showing a long period during which general treatment was given and a shorter period during which treatment with guaiacol was given. The solid area on the bottom shows in ounces the gradual decrease in the twenty four hour sputum output after treatment was begun. The chart shows a gradually lowering temperature until normal was reached. The roentgenograms reading from left to right were taken July 6 1932 shortly after admission, August 22 Jan 26 1933 Feb 25 March 9, June 12 1933 a few days after discharge and the last in October 1935 after a two year follow up in the clinic.

genogram showed infiltration of the lower part of the left upper lobe. In May 1931 a bronchogram with iodized oil revealed a cavity in the lower part of the left upper lobe close to the cardiac shadow, filled with opaque material.

The patient continued raising a large amount of foul sputum and his temperature was elevated. Intravenous injections of guaiacol and iodide were given every third day. The sputum lost its foul odor and diminished in amount, the patient was then symptom free.

In January 1932 the patient developed pain in the left side of the chest, and a cough with from 1 to 2 ounces (30 to 60 cc) of watery sputum but no elevation of temperature. After rest in bed with a series of intravenous injections for one month the roentgenograms showed irregular fibrosis between the first and the fourth ribs, on the left.

One year later an x-ray film showed irregular fibrosis in the left upper lobe and several areas of decreased density. The patient has been symptom free and doing his daily work since December 1932.

CASE 9—P D D, a white man aged 24 a painter, was admitted May 21, 1932, with a history of a cough productive of small amounts of blood since February 1932 when he had

one week with fever, general body pain and fatigue and had coughed up a small amount of blood. The cough continued and expectoration became profuse until May 1932, when it became blood streaked and foul. On admission the temperature was elevated and septic in character. The patient was emaciated. The daily expectoration measured from 4 to 10 ounces (120 to 300 cc) and was negative for acid-fast bacilli. The blood Wassermann reaction was negative. An x-ray film revealed a large infiltrative lesion in the right upper lobe with the trachea pulled to the right. Bronchoscopy revealed a mass projecting from the medial wall of the right main bronchus 28 cm from the upper incisor teeth, and above it to the right upper lobe a bronchial opening. A biopsy showed it to be a bronchial polyp.

The temperature continued septic for one month and the general condition remained unchanged. Guaiacol and iodide injections intravenously were begun, the temperature remained septic for the next twenty-five days and the daily sputum output increased in amount but was no longer foul. The temperature and output then decreased until his discharge September 23 when the sputum output was nil. A roentgenogram showed marked fibrosis in the right upper lobe.

In August 1933 he began coughing up blood-streaked sputum and lost weight rapidly. An x-ray film showed a large new growth in the right hilar region extending into the right upper lobe. The patient died of spontaneous pneumothorax, Nov 5, 1933.

Reexamination of the x-ray plates showed that the original condition was a new growth of the bronchus with a superimposed abscess.

CASE 11—M S, a white man, aged 47, a clerk, was a chronic alcoholic addict. He began to cough in April 1932, after being on a drunken spree. Expectoration became profuse and foul. In June he was treated at another hospital for a lung abscess and was discharged after three weeks feeling greatly improved, expectoration being very slight. He remained well until September 15, when he developed a cough productive of very foul and profuse sputum. He was treated at home by his physician but did not improve. He was admitted to the Fourth Medical Division Dec 15, 1932. The temperature was septic, expectoration was profuse and foul, and his teeth were in very poor condition with marked gingivitis. A roentgenogram showed a large cavity with fluid level in the right upper lobe.

The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. The patient was unimproved after twenty days of bed rest and postural drainage.

After intravenous injections of guaiacol and iodide the temperature began to fall, and the patient insisted on leaving the hospital. However treatment was continued at home. After one month the temperature became normal with diminution of the daily output of the sputum and it lost its foul odor.

Five months after treatment was instituted the patient returned to his usual work, being symptom free.

CASE 12—C S, a Negress, aged 55, a houseworker, was admitted July 5, 1932, with a history of a severe cough since February 1932 following a "bad cold." She had lost 15 pounds (7 Kg) and had occasional chills and profuse foul and blood-streaked sputum. On admission it was found that there was a definite glycosuria, the blood sugar being 250 mg per hundred cubic centimeters. The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative.

The patient was treated in another service until Feb 6, 1933. During the interval the x-ray film showed an infiltrative lesion involving the right upper lobe.

Expectoration varied from 6 to 20 ounces (180 to 600 cc) daily. The patient became progressively worse and surgery was inadvisable because of her poor general condition. Feb 17, 1933, guaiacol and iodide injections were begun and continued every third day. There was a gradual fall in temperature and decrease in the daily sputum output with a disappearance of its foul odor. The patient regained her appetite. The x-ray plates for the first time showed the beginning of definite clearing of the right upper lobe.

On discharge the patient was symptom free with normal temperature and 3 ounces (60 cc) daily output of sputum. The x-ray examination showed fibrosis in the right upper lobe. In October 1935 the patient was still symptom free and the sputum output nil. The x-ray film showed fibrosis with numerous small cavities in the right upper lobe.

CASE 13—J V, a white man aged 44, a porter, was admitted Nov 19, 1932, with a two months history of a cough productive of a large amount of foul smelling blood streaked sputum. Loss of weight had occurred and he was easily fatigued. On admission the temperature was elevated. The daily sputum output averaged from 15 to 18 ounces (450 to 540 cc) and was negative for acid fast bacilli. The blood Wassermann reaction was negative. His teeth and gums were in very bad condition. An x-ray plate showed a large cavity in the right upper lobe with infiltration extending up to the apex.

Intravenous injections of guaiacol and iodide were given every third day. The temperature dropped to normal and the sputum output diminished until it was nil on discharge March 7, 1933. A x-ray film showed fibrosis in the right upper lobe and about the right hilar region.

CASE 14—J A, a white man aged 47, a laborer, was admitted Dec 1, 1932, with a history of having been operated on for a left lower lobe abscess five years previously. Since then he had had a productive cough but was otherwise well until

three months before admission when he developed fever pain in the left side of the chest and paroxysms of coughing with foul expectoration. He had lost pounds since the onset of this illness in September 1932.

On admission his temperature was 103. The daily sputum output ranged from 18 to 20 ounces (540 to 600 cc) and had a foul odor. Intravenous injections of guaiacol and iodide were given every third day. At first the daily sputum output increased to 30 ounces (900 cc) but the odor decreased and the temperature dropped remaining between 98 and 99.8. X-ray films showed a cavity with a fluid level in the left lower lobe. After months of treatment the cavity decreased in size, as evidenced by x-ray examination the temperature was normal the daily sputum output was from 4 to 6 ounces (120 to 180 cc) and was odorless. The patient left the hospital against our advice, April 25, 1933, because he felt very well.

He was readmitted July 11, 1933, because of pain in the left side of the chest and a productive cough. X-ray examination showed infiltration of the entire left lower lobe with a cavity and a fluid level. There was from 10 to 12 ounces (300 to 360 cc) daily output of sputum and the temperature ranged between 99 and 101. Injections every third day produced a gradual decrease to 3 ounces (90 cc) daily of odorless fluid sputum the temperature became normal and x-ray films showed marked fibrosis of the entire left lower lobe with no definite cavity.

At present the patient is employed as an iron worker still having a cough productive of from 1 to 2 ounces (30 to 60 cc) of odorless fluid sputum.

CASE 15—M M, a white man aged 36, a waiter, was admitted Jan 27, 1933, with a history of cough and high fever of one weeks duration. This was complicated by a severe diabetes requiring 30 units of insulin three times a day. He had pneumonia in 1931.

On admission the diagnosis was made of an unclassified type of pneumonia of the right upper lobe. The diabetes was controlled with great difficulty. The signs in the chest did not clear and the temperature remained elevated. He continued to cough and raised small amounts of sputum. A roentgenogram February 23 showed a large area of infiltration at the periphery of the right upper lobe. November 31 the x-ray film showed an area of lessened density with fluid level. The patient was raising from 4 to 6 ounces (120 to 180 cc) of sputum daily. April 7, 1933, injections of guaiacol and iodide were begun and given every fourth day. The temperature fell to normal, remaining so and the sputum output decreased until it was nil one month before discharge May 13, 1933.

At the present time the patient is perfectly well and has no complaints. The diabetes is controlled and he attends the diabetic clinic regularly.

CASE 16—M G, a white woman aged 58, an interior decorator, was admitted March 24, 1933, with a history of being troubled with a cough since December 1932. In February 1933 she developed pain in the left side of the chest, anorexia, weakness, fever and a productive cough with foul thick sputum, which had all continued and become more troublesome.

The temperature was 101 and fluctuated between 101 and 104. The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. X-ray studies showed an area of infiltration in the upper left lobe with a large cavity with a fluid level.

The patient was given intravenous injections of guaiacol and iodide every third day. After fifteen days the temperature fell and the daily output of sputum decreased from 8 to 3 ounces (from 240 to 60 cc). The patient insisted on leaving the hospital against advice on May 5 after her temperature had been normal for twenty-five days and daily sputum output was only 1 ounce (30 cc). An x-ray plate showed that the area of infiltration had partially disappeared but the outline of the cavity was still visible.

She went to a summer resort and late in August developed a nonproductive cough. She was readmitted Nov 21, 1933. The temperature was elevated the sputum output ranged from 8 to 10 ounces (240 to 300 cc) daily and x-ray plates showed numerous small cavities with one large cavity in the left upper lobe. Despite intravenous injections of guaiacol and iodide a low grade temperature and daily sputum output of from 8 to

10 ounces (240 to 300 cc) persisted. Roentgenograms showed no improvement and she was discharged May 12, 1934. She died of a chronic lung abscess April 9, 1935.

CASE 17—I J, a white man, aged 41, a laborer, was admitted May 23, 1933, with a history of a cough productive of foul sputum following an alcoholic debauch one month previously. Two weeks prior to admission the patient had a hemoptysis, which had been repeated every morning since then.

The sputum was negative for acid-fast bacilli. The blood Wassermann reaction was negative. An x-ray film showed a large cavity in the right upper lobe with a fluid level and an area of infiltration around it. The temperature was 100 and the sputum output was 10 ounces (300 cc) daily.

Intravenous injections of guaiacol and iodide were given every second and third days, and the patient showed marked improvement. His appetite improved, the sputum was less foul, but the temperature continued to fluctuate between 101 and 105 for two months, when it finally dropped and the sputum output was only 1 ounce (30 cc) daily. X-ray studies showed only a slight fibrosis in the right upper lobe, with no definite evidence of a cavity.

The patient was discharged Sept. 22, 1933, and has remained perfectly well up to the time he was last seen, in August 1935.

CASE 18—K W, a white woman, aged 35, a housewife, was admitted May 8, 1933, with a history of being a heavy drinker of alcoholic liquors, complaining of a loss of 25 pounds (11 Kg.) within the past few years and a tired weak feeling.

The patient had a septic temperature and raised large amounts of foul sputum, averaging about 8 ounces (240 cc) daily. X-ray examination revealed an area of infiltration in the right upper lobe, with a definite area of decreased density with a fluid level. She was given intravenous injections of guaiacol and iodide every third day. The odor of the sputum disappeared and the amount, which at first increased, later diminished. After two months of treatment, the temperature was normal and she felt greatly improved. She left the hospital against advice, July 31, because we advised her to have her decayed teeth extracted and infected gums treated. An x-ray film on discharge showed only a small area of infiltration in the left hilar region.

Jan. 6, 1934, the patient returned to the clinic with a history of exposure to inclement weather and a productive cough with odorless sputum. X-ray films showed an area of infiltration extending from the left hilar region into the left upper lobe.

The patient reentered the hospital January 27, with a temperature of 102 and 20 ounces (600 cc) daily sputum output. She refused to have a number of decayed teeth extracted and also refused treatment. During the first thirty-five days of hospitalization, the temperature continued to be septic and the daily sputum output ranged from 8 to 12 ounces (240 to 360 cc). She was then given intravenous injections every third day, after which the temperature dropped to normal and the sputum output decreased. The patient again left the hospital against our advice, April 8, and the x-ray examination showed an area of fibrosis in the left upper lobe.

The patient remained well and symptom free until October 16, when she was readmitted in coma and died without regaining consciousness. Autopsy revealed a right subdural hemorrhage (traumatic), enlarged fatty liver and a small abscess cavity in the left upper lobe extending down into the left lower lobe.

CASE 19—T S, a white man, aged 65, a fireman, was admitted July 7, 1933, with a history of fever and productive cough following an alcoholic debauch. He was treated for pneumonia for three weeks but did not clear up and x-ray examination revealed a definite cavity with a fluid level in the right upper lobe.

On admission his temperature was 102. The daily sputum output ranged from 10 to 20 ounces (300 to 600 cc). Two weeks after admission, treatment with intravenous injections of guaiacol and iodide every third day were begun. The temperature fell to normal and the daily sputum output decreased and lost its foul odor. On discharge, September 20, the daily sputum output was 1 ounce (30 cc) daily with no odor and the patient felt perfectly well. X-ray studies showed some fibrosis in the right upper lobe with no evidence of cavitation.

CASE 20—P B, a white man, aged 39, a tailor, was admitted Feb. 19, 1934, complaining of a cough, productive of from 8 to 15 ounces (240 to 450 cc) of thick, foul smelling sputum. He also complained of dull pain in the left side of the chest about the third space near the sternum, and a loss of 6 pounds (2.7 Kg.) in the past month.

On admission the temperature was 102 and continued to show a septic course. The sputum output ranged from 8 to 16 ounces (240 to 480 cc) daily and was very foul.

Two weeks after admission the injections of guaiacol and iodide were begun. Within four weeks after the injections were started the temperature fell to normal, and the sputum output diminished. Eight weeks after treatment was begun the patient was symptom free and the x-ray examination showed the lungs to be clear except for bilateral hilar adenopathy.

COMMENT

The results have been satisfactory and it is noteworthy that Unger,⁶ using an injectable guaiacol solution, obtained similar results at the Rudolf Virchow Hospital in Berlin. In the present study of twenty treated cases, it was found that the patients felt considerably better in a very short time, owing to the subsidence of the fever and cough and to the decrease of the daily sputum output and the loss of its foul odor. Serial roentgenograms showed early regression of the large area of pneumonitis surrounding the abscess cavity and later its actual disappearance.

It is felt that the eradication of all foci of infection about the mouth, nose and throat and moderate restriction of all activities until the roentgenogram shows complete healing is very essential if the results of this type of treatment are to be permanent. Of the four deaths in this series, one was due to a malignant condition of the lung, one to traumatic subdural hemorrhage, and two to recurrence of the abscess. It is well to point out that the abscess reappeared in those patients who refused to have their infected gums treated.

Because many lung abscesses heal spontaneously and because of the danger of early operation, most authorities agree that acute lung abscesses should be treated medically from six to twelve weeks before any surgical procedures are resorted to. Yet, after reviewing the literature, one is impressed with the lack of active medical treatment during this period. As the intravenous use of guaiacol causes early subsidence of the symptoms and a regression of the pathologic condition in the lung without producing any unfavorable reactions, it appears that this type of therapy should be used in the treatment of patients with acute and chronic lung abscess.

Novelties and Chance Findings—The present stress laid in this country upon the preclinical laboratory courses, particularly those in chemistry and physiology, has greatly influenced the entire point of view of the physician who must have a calorimeter and an electrocardiograph with a technician to operate them, if only to keep in fashion, little realizing that they are scarcely more than research instruments. There has been much talk about the modern physiological schools of physics and surgery and I presume this means that it is less fashionable for the clinicians to grub in the pathological and anatomical laboratories than formerly. No doubt this is the case. Anatomy and pathology just now appear to the unimaginative to have been thoroughly explored, the pioneers have taken the surface washings, and rather than dig deep for gold we prefer to look elsewhere for novelties and chance findings—Cushing, *Harvey, Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

FACTORS RESPONSIBLE FOR FAILURE FURTHER TO REDUCE INFANT MORTALITY

HERMAN N BUNDESEN, MD, ScD
President Chicago Board of Health

WILLIAM I FISHBEIN, MD

O A DAHMS, MD

AND

EDITH L POTTER, MD

CHICAGO

The death rate of infants from 7 days to 1 year of age, in the United States registration area, has been reduced 53 per cent during the years 1916 to 1934 inclusive. During the same time the death rate of infants under 7 days of age has been reduced only 10 per cent.¹ In order that infant mortality may be further materially reduced, the chief effort must be to prevent deaths under 2 weeks of age and particularly to prevent those that occur during the first few days of life. Before such an effort can be successful, the causes of early infant deaths must be accurately determined. When the actual causes of infant deaths are known, measures can be more effectively devised to prevent them.

The number of infant deaths under 7 days of age has not been reduced to a greater extent because little has been generally known as to the relative frequency and importance of the various causes of neonatal² deaths. Those who suspected the situation were not in a position to reduce the infant mortality.

SOURCE OF STATISTICS

To determine accurately the cause of an infant's death, particularly in the neonatal period, first, a satisfactory necropsy must be performed by a pathologist thoroughly familiar with infant pathology; second, careful consideration must be given by well trained physicians to the clinical history and laboratory results. Therefore in Chicago during 1936, whenever an infant died a complete necropsy was obtained, if possible. An investigation of the clinical history and available laboratory results for every infant who died was made by trained workers. A complete obstetric history was obtained in every case.

Whenever a necropsy was performed, a written record or protocol, covering all the facts, was obtained. This protocol, together with the entire record of the investigation of each case, was reviewed by a committee including pathologists, pediatricians and obstetricians. After consideration of the entire record—clinical, laboratory and pathologic—a conclusion was reached as to the most probable cause of death in each case.

STANDARDS OF SATISFACTORY NECROPSIES

The committee mentioned set up standards by which a necropsy was evaluated as satisfactory or unsatisfactory. To be considered satisfactory, a necropsy (1) must have been done by a competent pathologist, familiar with fetal and infant pathology, and (2) must have included an examination

of the brain and cranial cavity, (3) must have included a microscopic examination of the tissues, if necessary to make an accurate diagnosis, and (4) must have included a complete, written report of the results. Whenever the necropsy was limited, but the cause of death was obvious from the examination made, it was also considered satisfactory.

In Chicago, during 1936, 1,848 infants died under 1 year of age. Necropsies were performed on 798, or 43 per cent,³ of them. Based on the standards given, 645, or 81 per cent, of these necropsies were accepted as satisfactory.

The investigation revealed that many of the necropsies done on infants during the neonatal period were unsatisfactory because they had been delegated to untrained men to teach them necropsy technique. In other instances, necropsies were indifferently performed by well trained men who had little interest in making any real effort to determine the correct cause of death.

In view of the fact that permission to perform necropsies is often difficult to obtain, the waste of material as a result of inadequate or careless necropsy technique is noteworthy.

METHODS OF ASSIGNING DEATHS

The health officer bases his efforts to prevent infant deaths on information obtained chiefly from two sets of figures: (1) from the causes of death taken from the death certificates of his own locality and (2) from the causes taken from the death certificates of the entire United States registration area. Both these groups of causes are classified according to the rules of the International List⁴ as well as the Manual of Joint Causes.⁵

Both these sets of figures are, as a rule, inaccurate and misleading because they are made up from the causes of deaths taken from death certificates. These causes, particularly for infants under 2 weeks of age, in a large number of cases are not correct (and usually cannot be unless a satisfactory necropsy is performed). The figures become more misleading when the causes are classified according to the rules of the International List and the Manual of Joint Causes, since, as a result of this classification, a death is often charged to a cause that has little or no relation to the real reason for the infant's death.

ERRORS DUE TO THE GROUPING OF TERMS IN THE "INTERNATIONAL LIST"

The grouping of terms on death certificates by the rules of the International List often hides the true cause of death by throwing together, under a single heading, a variety of conditions. For example, such conditions as infection of the umbilical cord, hemorrhagic disease of the new-born, and asphyxia are classified in the group Other Diseases Peculiar to Early Infancy in the International List.

The health officer, in studying these figures, cannot tell from the grouping Other Diseases Peculiar to Early Infancy what preventive measures may reduce

3 From Jan. 1 to June 1 1937 necropsies were performed on 500 or 60.5 per cent of 827 infants who died.

4 The International List of Causes of Death is a list of all the terms which might be used on a death certificate grouped under 200 headings, each heading having a code number. The various terms are required to be charged to the code number under which they are listed. When the term International List is used it denotes the International List of Causes of Death.

5 The Manual of Joint Causes is a list of the same 200 headings that appear on the International List and shows to which heading a death should be assigned when two or more causes appear on a death certificate.

The authors received the assistance and cooperation of physicians in Chicago who with the hospitals made available for this study their records and case reports of infant deaths.

1 The period from 1916 to 1934 inclusive is used because figures for the deaths under 7 days in the registration area before 1916 and after 1934 are not available for comparison.

2 When the term neonatal is used in this article the period under 15 days is meant.

the number of deaths from the various causes included under this heading. However, if the conditions actually causing infant deaths are known by the health officer, he can often outline helpful procedures to prevent them. Thus much can be done by proper technic to prevent infections, while hemorrhagic disease may be treated successfully by transfusion in many cases. Furthermore, asphyxia may at times be prevented by proper obstetric care.

Such conditions as atresia of the rectum or pyloric stenosis, which might be obvious causes of death, as well as others, such as epispadias and syndactylism, which could not in themselves be causes of death, are thrown together in the group called Other Congenital Malformations.

The lives of a number of infants, even with the more serious of these disorders, might be saved by using proper procedures. For instance, in imperforate

anatomically open for as long as three or four months after birth. In such a case the real cause of death remains unknown.

ERRORS DUE TO THE PREFERENCE GIVEN CERTAIN CONDITIONS BY THE MANUAL OF JOINT CAUSES

Under the rules of the Manual of Joint Causes, not infrequently a death is charged to some condition not responsible for it.

For example, if such causes of death as prematurity or bronchopneumonia are included on the death certificate with patent foramen ovale, the death would still be charged to Congenital Malformations of the Heart, because congenital heart disease takes precedence over pneumonia or prematurity. We know that congenital heart disease, to which the death is charged because of the patent foramen ovale, probably had nothing whatever to do with causing it. Thus the true cause of death, such as pneumonia, for which the health officer might devise preventive measures, is hidden.

If a prematurely born infant under 15 days of age dies of infectious diarrhea, and prematurity and diarrhea appear on the death certificate, the death is charged to premature birth.

If an infant born by cesarean section dies from pneumonia during the neonatal period, and pneumonia and cesarean section both appear on the certificate, under the rules of the Manual of Joint Causes the death is charged to birth injury with cesarean section, when it really should be charged to pneumonia.

Chicago Facts—To overcome the difficulty arising from a lack of reliable figures on which to plan a campaign to reduce neonatal mortality in Chicago, steps first were taken to collect the facts (not only the figures). Then after the facts were collected, they were dispassionately analyzed. Finally, based on the analysis of these facts, additional and more definite procedures than formerly used were set in motion to reduce the number of infant deaths.

Crude Rates—In 1934 Chicago's death rate for infants under 1 year of age, per thousand live births, was 47.7. This was higher than that of a number of other large cities. In 1936 Chicago's infant death rate was 38.5. This was the lowest submitted by any of the twelve largest cities in the United States.

There was a reduction of 11.5 per cent in the death rate of infants under 7 days of age during the two year period 1935 and 1936. This decrease helped materially in bringing about Chicago's death rate of 38.5 for infants under 1 year of age.

This reduction of 11.5 per cent followed the institution of the procedures⁶ for preventing neonatal deaths started in 1935 and continued and amplified thereafter. These procedures were based on the information obtained by satisfactory necropsies and clinical investigations and were amplified as better and more satisfactory necropsies were performed.

COMPARISON OF THE CAUSES OF NEONATAL DEATHS WITHOUT NECROPSIES WITH THE CAUSES DETERMINED BY SATISFACTORY NECROPSIES

Of the 1,848 infants who died under 1 year of age during 1936, 1,123 or 61 per cent, were under 15 days of age. As we have stated, it is particularly

TABLE 1—Leading Causes of 398 Neonatal Deaths Determined by Satisfactory Necropsies (Not Classified by the Official Classification*)

	Cases	
	Number	Per Cent
Cerebral hemorrhage	102	25.6
Congenital malformations	63	15.8
Pneumonia (all types)	35	8.5
Asphyxia	13	3.3
Pulmonary hemorrhage	8	2.0
Edema of the brain	7	1.8
Erythroblastosis	6	1.5
No demonstrable pathologic conditions	123	30.9
(a) Viable infants with marked atelelectasis	37	9.3
(b) Infants showing marked immaturity or born of mothers with pathologic conditions or both	53	20.8
(c) Full term infants with no atelelectasis or maternal factors	3	0.8

* Whenever the term 'official classification' or 'officially classified' is used it refers to the method of classification required by the International List of the Causes of Death as well as by the 'Manual of Joint Causes'.
† See discussion of atelelectasis. The previable premature infants with atelelectasis are included with those having no pathologic condition.

anus and congenital intestinal obstruction, early operation may occasionally save the infant. Early diagnosis of pyloric stenosis makes it possible, by proper treatment, to save the baby. In instances such as anencephalus, nothing can be done. However, the health officer in studying the figures based on the International List has no way of knowing what procedures should be instituted to prevent deaths in this group.

In general the International List, instead of containing only those disorders which might cause death, includes almost every disorder, whether possibly fatal or not.

Thus, if some condition that does not cause death is written on the death certificate, some means of classifying it as a cause of death can be found by using the International List. For example, if cesarean section appears on the death certificate, the death is grouped under Injury at Birth. This only serves to mislead the health officer who uses these figures.

As occurs with the grouping Other Congenital Malformations the group Congenital Malformations of the Heart also includes conditions that are not responsible for deaths such as patent foramen ovale and patent ductus arteriosus.

At present if the death certificate shows the cause of death as patent foramen ovale the death would be classified as one from congenital heart disease. However a patent foramen ovale is a normal condition in the new-born infant and the foramen may continue

⁶ Bundesen H N, Dahms O A, Fiehlman W J and Harmon G F. Mortality of New Born Infants in Chicago during 1935. J A M A 107: 270-276 (July 25) 1936.

in this neonatal group that the evidence indicating the causes of infant deaths is not generally known

Of these 1,123 infants who died under 15 days of age, satisfactory necropsies were performed on 398, or 35.5 per cent, and unsatisfactory necropsies on 117, or 10.4 per cent. No necropsies were done on 608, or 54 per cent. In the 398 neonatal deaths in which there were satisfactory necropsies and in which the clinical investigations and laboratory observations were studied, the eight leading causes of death accounted for 90.4 per cent of all the deaths in that group.

In the 608 infants dying under 15 days of age on whom no necropsies were performed, the eight leading causes of death as stated⁷ by the physicians on the death certificates were as given in table 2.

EVIDENCE THAT THE CAUSE OF DEATH AS GIVEN ON THE DEATH CERTIFICATE (WITHOUT NECROPSY) MAY BE INACCURATE

To determine the importance of necropsies, the eight leading causes of death found in the 608 infants dying under 15 days of age on whom necropsies were not performed (table 2) should be compared with those found in the 398 infants on whom satisfactory necropsies were done (table 1). In such a comparison it will be noticed in the group with no necropsies that prematurity is the leading cause (41 per cent). In the group with necropsies, such deaths as occurred from prematurity are included in the 30.9 per cent that were classified under the heading "No Demonstrable Pathologic Conditions." The reason for this difference is discussed later in the section under "Premature Infants."

Atelectasis is second on the list of causes without necropsies. It is stated as the cause of death in 14.7 per cent of this group. As atelectasis is a secondary lesion, it was not accepted as a cause of death in the series with necropsies. Infant deaths in which there was no pathologic condition other than marked atelec-

TABLE 2—Leading Causes of 608 Neonatal Deaths as Stated by Physicians Without Necropsy (Not Classified by the 'Official Classification')

	Cases	
	Number	Per Cent
Prematurity	249	41.0
Atelectasis	89	14.7
Cerebral hemorrhage	77	12.7
Congenital malformations	74	12.2
Asphyxia	45	7.4
Pneumonia (all types)	17	2.8
Injury at birth other than cerebral hemorrhage	10	1.6
Icterus neonatorum	9	1.5

tasis were put in the group of those with "No Demonstrable Pathologic Conditions."

Cerebral hemorrhage is third on the list of causes without necropsies. It is found twice as often in the group with necropsies as in the group without.

Congenital malformations is the fourth cause in the group with no necropsies, and the second cause in the group with necropsies.

Asphyxia is fifth on the list without necropsies. It is stated to be the cause of death more than twice as often in this group as in the group with necropsies. On the other hand, pneumonia (all types) is sixth on

⁷ Many death certificates contain two or more causes of death. The reviewing committee in cases in which two or more causes appeared on the death certificate assigned the death to what it believed was the most probable cause.

the list and is stated to be the cause of death only one third as often in the group with no necropsies as in the group with necropsies.

This indicates the difficulty of diagnosing pneumonia clinically in the neonatal period. Furthermore, even when making the diagnosis by necropsy a microscopic examination of the lung tissue must be included, since on gross examination the pneumonia may be missed or may occasionally be erroneously diagnosed. It is frequently impossible to tell the difference grossly between the lung partially atelectatic and engorged with blood and the lung with pneumonia.

TABLE 3—Leading* Causes of the 1,123 Neonatal Deaths When Classified by International List and the Manual of Joint Causes

	Cases	
	Number	Per Cent
Premature birth	501	44.61
Injury at birth	283	25.20
Congenital malformations	143	12.70
Other diseases peculiar to early infancy	110	9.79
Pneumonias (all types)	42	3.73
Diseases of the thymus gland	10	0.89
Congenital syphilis	7	0.62
Congenital debility	4	0.35

* Infanticide is the seventh cause but is not listed since the figures would be the same in all tables.

Injury at birth other than cerebral hemorrhage is stated as a cause in the group with no necropsies, while it does not appear in the eight leading causes in the other group. On the other hand, edema of the brain appears among the first eight causes of death in the group with necropsies and is not found in the group without them.

This comparison between the eight leading causes of neonatal deaths, as determined by necropsies, and the causes as stated without necropsy shows that there is a difference in the relative frequency and importance of the various causes of neonatal deaths and indicates the importance of postmortem examinations in determining the correct cause of deaths. Although it is realized that the collected information is not sufficient to solve the problem of the causes of neonatal deaths, the 398 cases with satisfactory necropsies do give a good idea as to the nature of the problem.

COMPARISON OF THE CAUSES OF NEONATAL DEATHS "OFFICIALLY CLASSIFIED" WITH THE CAUSES DETERMINED BY SATISFACTORY NECROPSIES

If all the causes of death in the 1,123 infants dying under 15 days of age (which includes the 607 without necropsies, 398 with satisfactory necropsies and 118 with unsatisfactory necropsies) are classified according to the rules of the International List and the Manual of Joint Causes the distribution of the eight leading causes of death is as given in table 3.

EVIDENCE THAT CERTAIN CAUSES OF DEATH ARE INACCURATELY ASSIGNED BY THE "OFFICIAL CLASSIFICATION"

To reveal the manner in which the "official classification" hides certain causes of death, the eight leading causes in table 3 should be compared with those in table 1.

Prematurity—In the grouping just made (which is the misleading type usually employed in planning procedures to reduce infant mortality), premature birth is the first cause. It is listed as the cause of death in 501, or 44.6 per cent of all the infants who died

under 15 days of age, an even greater percentage than in the series without necropsies not grouped by the "official classification" On the other hand, those premature infants on whom necropsies were done and in whom no pathologic lesion was discovered are included with the 123 cases listed as "No Demonstrable Pathologic Conditions" in table 1 Of the 123 infants in whom no pathologic lesion was discovered at necropsy, eighty-two were premature infants whose mothers did not have complications that might have contributed to

stated to be due to this condition In the group with necropsies in table 1, 158 per cent of the deaths were found to be due to congenital malformations Moreover, a number of deaths charged to patent foramen ovale are included in the "officially classified" group, but patent foramen ovale is not a cause of infant deaths Furthermore, there is no means of knowing which of these malformations reported as causing death in the "officially classified" group were really responsible for death Hence the percentage given may be entirely misleading In the group with necropsies, only those deaths were assigned to congenital malformations in which the malformation was the direct cause of death

Other Diseases Peculiar to Early Infancy—This is given as the fourth cause of death in the "officially classified" group, accounting for 110, or 9.79 per cent, of the deaths This heading includes such conditions as asphyxia, icterus and particularly atelectasis, which was not accepted at all as a cause of death in the series with necropsies

Atelectasis—In the series with necropsies, the committee assigned deaths in which there was no pathologic condition other than atelectasis to those with "no demonstrable pathologic condition" This action was taken because the expansion of the lungs after birth is a gradual process and some degree of atelectasis is almost a universal condition in the lungs of the premature infant during the first few days It is also frequently present in the lungs of the full-term infant during this period

Furthermore, atelectasis, even when almost complete, is a secondary condition dependent on some other condition, such as depression of the respiratory center This depression in turn may be due to the pressure from cerebral hemorrhage, to interference with oxygenation of the infant's blood during labor, or to narcosis brought on by the excessive use of analgesics in the mother during labor When it is more generally realized that the excessive use of narcotics may cause atelectasis and thus lead to the infant's death, steps will surely be taken to limit their administration

TABLE 4—Leading Causes of 243 Neonatal Deaths in Premature Infants Determined by Satisfactory Necropsies (Not Classified by the "Official Classification")

	Cases	
	Number	Per Cent
Cerebral hemorrhage	56	22.0
Pneumonia (all types)	19	7.8
Congenital malformations	18	7.4
Asphyxia	9	3.7
Edema of the brain	7	2.9
Congenital syphilis	3	1.2
Erythroblastosis	2	0.8
No demonstrable pathologic condition	111	45.6
(a) Viable infants with marked atelectasis	30	12.3
(b) Infants showing marked immaturity or born of mothers with pathologic conditions or both	81	33.3

the death In other words, in these eighty-two infants, or 20.6 per cent of the 398 cases with necropsy, the only known factor that may have been responsible for the death was prematurity

Cerebral Hemorrhage—In the classified group in table 3, injury at birth is given as the second cause Two hundred and eighty-three, or 25.2 per cent, are thus listed In the group of deaths with necropsies in table 1, injury at birth does not appear as such

However, in the group with necropsies, cerebral hemorrhage is first in the list as a cause of death, accounting for 102, or 25.6 per cent

In the International List, no separate heading for cerebral hemorrhage, as a cause of infant death, exists The rules require that this condition be included under injury at birth Therefore table 3, which lists the series officially classified, cannot carry cerebral hemorrhage as a distinct item

In the group with satisfactory necropsies, table 1, the term is used specifically, because the lesion was actually found However, no comparison of the two tables is possible with respect to cerebral hemorrhage, because the "officially classified" group embraces, under the title Injury at Birth, not only cerebral hemorrhage and all types of injuries but also a variety of conditions which may or may not have produced death, such as fractured clavicle, breech presentation, retarded labor, forceps operation, placenta praevia, hemorrhage into the lungs, knot in the umbilical cord, and born with a caul

Though it is required by the official classification that all these conditions be included under injury at birth, the total of these in the "officially classified" series is only 25.2 per cent, as compared with 25.6 per cent of cerebral hemorrhage alone in the group of necropsies

It is evident from this fact that many cerebral hemorrhages were not diagnosed when necropsies were omitted Furthermore, not all cerebral hemorrhages are injuries at birth

Congenital Malformations—In the "officially classified" group in table 3, congenital malformations is third Of the deaths in this group, 12.7 per cent are

TABLE 5—Causes of 372 Neonatal Deaths in Premature Infants Classified by International List and Manual of Joint Causes

	Cases	
	Number	Per Cent
Premature birth	297	79.8
Injury at birth	47	12.6
Congenital malformations	20	5.4
Other diseases peculiar to early infancy	6	1.6
Pneumonia	1	0.27
Congenital syphilis	1	0.27

Heretofore atelectasis, like prematurity, has been a scrap heap into which a large number of infant deaths has been thrown when the cause of death was not definitely known If physicians continue blindly to accept it as a cause of death, the correct causes will remain hidden

Pneumonia—Pneumonia was fifth on the list in the "officially classified" group and third on the list in the group with necropsies It was found almost three times as often in the infants with necropsies as in those in the "officially classified" group

This comparison between the leading causes of neonatal deaths when "officially classified" and the causes

as determined by satisfactory necropsies shows that certain causes of death are inaccurately assigned by the "official classification"

By comparing the number of times certain causes of death occur in the infants on whom necropsies were performed with the number of times they occur in the group classified according to the rules of the International List and the Manual of Joint Causes, it is seen how this classification may mislead health officers and others interested in preventive work. The International List hides causes by throwing together a large number of unrelated conditions under one heading. The manual of Joint Causes hides the true causes of death by charging a death to some condition not responsible for it.

NEONATAL DEATHS IN PREMATURE INFANTS

Of the 1,848 infants who died under 1 year of age in Chicago during 1936, 782, or 42 per cent, were premature, 681 of these, or 37 per cent, died under 15 days of age. Of these 681 neonatal deaths in premature infants, necropsies were performed on 309, or 45.2 per cent. Of these 309 necropsies 243, or 79 per cent, were satisfactory according to the standards established.

The classification of Dr. Fred L. Adair⁸ for degree of maturity was used, which states that a previable premature infant is from 400 to 999 Gm in weight, of twenty-two to twenty-eight weeks' gestation and from 28 to 35 cm long.

A viable premature infant is from 1,000 to 2,499 Gm in weight, of twenty-nine to thirty-seven weeks' gestation and from 36 to 46 cm long.

In the 243 premature infants, a study of satisfactory necropsies, clinical investigations and laboratory observations revealed that the eight leading causes of death were as given in table 4.

COMPARISON OF THE CAUSES OF NEONATAL DEATHS IN PREMATURE INFANTS OFFICIALLY CLASSIFIED WITH THE CAUSES DETERMINED BY SATISFACTORY NECROPSIES

Had the causes of death in the 372 infants on whom no necropsies were performed been classified according to the rules of the "official classification," they would be as given in table 5.

By comparing table 5, which gives the deaths classified by the "official classification" and which is the one usually employed by health officers in attempting to reduce the infant mortality, with table 4, which gives the causes shown by necropsies, it will be seen that the use of the "official classification" hides causes of death. In table 5 the "officially classified" series, 79.8 per cent of the deaths are assigned to prematurity. In fact, so many deaths are thrown into this group by the "official classification" that a number of other causes, such as icterus and asphyxia, are completely eliminated.

Premature birth in itself was probably the cause of death in a number of the eighty-one of the total of 111 infants in the series with necropsies in whom no pathologic lesion was discovered. It probably was a cause also in some of the thirty infants who were viable with no discovered lesion other than atelectasis.

Of these 111 premature infants on whom necropsies were performed (those with no lesions and those with atelectasis), fifty-seven, or 51.3 per cent, were previable, three were abortions and fifty-one, or 46 per cent, were viable according to the "Adair classifica-

tion." A premature infant who has not reached a sufficient degree of maturity may die within a few minutes or a few hours, without any demonstrable cause other than mere prematurity. The three abortions in this series obviously were in this group.

However, as the period of uterogestation increases, the mortality rate tends to decrease. Furthermore, as the period of uterogestation increases, causes of death in addition to prematurity are more likely to be found.

In our experience, pathologic lesions in addition to prematurity have been found in many instances, even in previable premature infants. Thus, of a total of seventy-nine previable premature infants on whom necropsies were done, definite pathologic conditions, such as cerebral hemorrhage or pneumonia were found in twenty-two infants, or 28 per cent. These deaths were probably due to prematurity, even though other lesions were present, since these infants all weighed less than 1,000 Gm.

However, before deciding on the percentage of the series with necropsies in which the cause of death was due to prematurity alone, the maternal factors must be taken into account. Such maternal conditions as toxemia, placenta praevia and abruptio placentae may play some part in producing the death of an infant. These conditions might not produce demonstrable lesions.

Of the group in which no demonstrable pathologic conditions were found, as stated, three were abortions, fifty-seven were previable and fifty-one were viable premature infants. In these previable and viable premature infants, maternal factors, which might have caused death, were present in twenty-six, or 23 per cent.

This still leaves eighty-two, or 33 per cent of the 243 cases with necropsies in which the cause of death may be stated as due to prematurity, as compared with 79.8 per cent in the "officially classified" group.

With proper care, in many instances, a premature infant's life may be saved and pathologic conditions kept from developing. This does not mean that prematurity is not a contributing factor in causing death. Therefore to us it seems better in the case of a strong, viable premature who dies with no discoverable pathologic lesions or any cause on the maternal side to consider the cause of death as undetermined rather than to judge the death as due to prematurity alone.

The percentage of deaths stated to be due to injury at birth in the officially classified group is two thirds of that shown to be caused by cerebral hemorrhage alone in the group with satisfactory necropsies.

This is a striking difference and indicates that cerebral hemorrhage is a more frequent cause of death in premature infants than is generally recognized. Sixteen of these infants with necropsies, who had cerebral hemorrhage, were previable. If these sixteen deaths are considered as due to prematurity rather than to cerebral hemorrhage, there are still forty, or 16.4 per cent, of the deaths due to cerebral hemorrhage.

Pneumonia was stated to be the cause of death in 0.27 per cent of the "officially classified" group and in 7.8 per cent of the group with necropsies or about twenty-nine times more often. One reason for this marked difference is the undue weight given to prematurity by the Manual of Joint Causes. These figures indicate that pneumonia is a cause of neonatal death in premature infants more often than is generally thought. A number of such pneumonias are probably due to aspiration of infected amniotic fluid.

⁸ Adair, F. L. Personal communication to the authors.

Edema of the brain was found in 29 per cent of the cases with necropsies but was not given as a cause of death at all in the group without necropsies, and yet, such edema appears to be frequent in premature infants delivered by cesarean section, for, of these seven premature infants who died of edema of the brain, five were delivered in this way. The significance of edema of the brain is not definitely known. The cranial cavity of a premature infant contains more fluid than that of a full term infant. When this fluid is present to an excessive degree, however, it is believed that it may have some pathologic significance.

Congenital malformations make up 54 per cent of the deaths in the "officially classified" group, as compared with 74 per cent in the group with necropsies, while atelectasis is given as 13 per cent in the "officially classified" group (included under the heading "Other Diseases Peculiar to Early Infancy"), as compared with none in the group with necropsies.

MAIN FACTORS RESPONSIBLE FOR A HIGH NEONATAL DEATH RATE

A study of the clinical investigations of neonatal deaths and the obstetric histories showed that there were four main factors which contributed greatly to these infant deaths: (1) maternal complications, (2) inept obstetric care, (3) incorrect or inadequate neonatal care, and (4) prematurity.

Maternal Complications—Complications in the mother were associated with 385 of the 1,123 infant deaths occurring during the neonatal period. The most common of these complications, in the order of their frequency, were toxemia, placenta praevia, accidents and injuries, abruptio placentae, syphilis and hypertension. All these complications and particularly toxemia, might be factors in the production of infant deaths.

The early diagnosis and treatment of maternal complications, therefore, are important in the reduction of neonatal deaths. In the presence of pathologic conditions in the mother, adequate antepartum care is essential.

Inept Obstetric Care—Inept obstetric care was found to be associated with a number of the deaths that occurred from cerebral hemorrhage. Cerebral hemorrhage was the leading cause of death in the infants on whom necropsies were performed.

Attempts to speed up delivery by the indiscriminate use of oxytocics, such as solution of posterior pituitary, the unindicated application and improper use of forceps and the unnecessary performances of version and extraction, were often followed by the death of the infant.

The use of analgesics, such as morphine, scopolamine and the barbiturates, during labor, adds to the hazards which many new-born infants face. With prematurity, cerebral hemorrhage or the effects of prolonged labor, the additional depression of the respiratory center by the analgesic materially increases the difficulty in establishing respiration.

Prematurity—The premature infant whose tissues have not developed sufficiently to function normally will not survive unless given special care. Some premature infants have such inadequately functioning tissue, particularly in the lungs, that they will not survive under any conditions. Immediate provision for the maintenance of normal body temperature, proper feeding, particularly the use of breast milk, protection against infection, and the use of oxygen are the four

main safeguards for the premature infant. (This subject was discussed previously⁶.)

Adequate care for premature infants should be provided to bring about further reductions in neonatal mortality.

Incorrect or Inadequate Neonatal Care—An essential part of correct neonatal care is the use of proper methods of resuscitation in reviving the asphyxiated infant. Investigations revealed that measures often are employed which are damaging to the infant, particularly those who are prematurely born. It is generally agreed that violent methods, such as slapping, swinging, hot and cold baths and ether sprays, are more liable to result badly than favorably.

On the other hand, the skilled use of the tracheal catheter is generally accepted as the best means of clearing the respiratory passages and initiating respiration. However, it was by no means employed as often as indicated.

Education in the proper methods of resuscitation is important to help in further reducing neonatal mortality.

The subject of maternal factors and inept obstetric care in causing neonatal deaths will be fully discussed in a separate article.

COMMENT

The figures prove that, while there has been a reduction in the number of deaths in infants under 1 year of age in the United States registration area, the greater part of this reduction has been in infants past 14 days of age.

Before procedures can be effectively carried out to reduce the number of deaths in the neonatal period, the accurate causes of these deaths must be determined. This can be done only by competently performed necropsies on large numbers of new-born infants.

The use of the "official classification" tends to hide certain causes of death and gives too much weight to others.

Since a series of satisfactory necropsies reveals that the leading cause of death is cerebral hemorrhage and that prematurity is a large factor in the production of many deaths, directly or indirectly, it is our feeling that the chief attack in reducing neonatal mortality should be centered on these two conditions.

There is need for further study of the factors responsible for prematurity.

The toxemias of pregnancy, which often result not only in premature delivery, both spontaneous and induced, but also in damage to the infant, are other factors contributing to infant deaths which need further investigation. However, the principal and most hopeful field of endeavor at the present time is to make certain that the infant is in skilled hands. The statement has been made that every mother is entitled to skilled care during delivery. We might add that the infant too is entitled to the same consideration.

CONCLUSION

1 Many of the causes of neonatal deaths, as stated on the death certificates, are incorrect, because of misdiagnosis.

2 The use of the International List and the Manual of Joint Causes in classifying causes of deaths is misleading in many cases.

3 The rules of the official classification result in many deaths being classified as due to prematurity when they are actually due to other causes.

4 Those conditions which are not responsible for deaths might well be deleted from the International List. Instead of putting such causes on the certificate, it is better to state that the cause of death is unknown, thus encouraging necropsies.

5 Premature infants who die might well be classified separately from full term infants. Additional causes found in these premature infants should be classified with the prematurity, such as prematurity and bronchopneumonia, prematurity and gastroenteritis and prematurity and cerebral hemorrhage, instead of being charged to prematurity and the other cause ignored.

6 Further reduction in neonatal mortality will require, among other things, efforts to prevent prematurity and to provide adequate obstetric care for every mother and infant.

7 Such other efforts as the health officer will make will be directed particularly toward the prevention of those causes of death which death certificates indicate to him occur most often. If, however, the causes given to him are incorrect, such efforts as he exerts will be futile. If he has the correct causes, there are many things which may be done to save lives.

When, for example, pneumonia and diarrhea are concealed by assigning deaths to prematurity, the faulty nursery technic that may be responsible for these deaths remains undetected and uncorrected. If the death certificate correctly designates cerebral hemorrhage as the cause of death instead of incorrectly designating prematurity or atelectasis, the health officer may discover that faulty obstetric care was a large factor, and he may establish certain safeguards to prevent future fatalities under similar circumstances.

Combating atelectasis alone, without attention to its underlying causes, will not save infant lives. On the other hand, when atelectasis is due to excessive use of analgesics, if the health officer knows that this is occurring, he can take steps to prevent such deaths.

Asphyxia on the death certificate, without further information as to its cause, will leave the health officer undecided as to the direction of the efforts he should make, whereas a knowledge of the maternal factors, such as abruptio placentae, placenta praevia or breech delivery, will point the way to methods of better protection for the child. In the same connection the proper procedures for attempting to resuscitate the asphyxiated infant are of outstanding importance. Likewise, better and immediate neonatal care, the use of the incubator for the prematurely born, the conservation of heat and body fluids, and many other measures are contingent on accurate information as to the causes of death which, by disclosing the lack of these things in many cases, will show the health officer how to provide for their use in the future.

Now that our knowledge of the causes of neonatal deaths is increasing through clinical investigations, more necropsies and better classification, the direction of future efforts in preventing neonatal deaths is more clearly indicated.

We must learn more of the prevention of prematurity. Why do one third of twin pregnancies terminate prematurely? Can they be carried to term? Has progesterone or vitamin E any value in extending the duration of pregnancy? Also the value of the early injection of whole blood should be determined in the treatment of cerebral hemorrhage, hemorrhagic disorders, prematurity, anemia and icterus of the newborn and erythroblastosis.

There is still much to be learned concerning the relationship of the maternal diet to the prevention of neonatal disorders. Will the administration of large amounts of vitamins B and D and dicalcium phosphate, during pregnancy, have a beneficial effect?

Can present methods be improved or more effective methods be devised for the resuscitation of asphyxiated infants? These and many other problems still await solution.

No help can be extended in any situation when the facts regarding it are concealed by carelessly filled out or incorrect death certificates, or methods of classification which emphasize the secondary and ignore the important and preventable causes. Realization of the correct causes of neonatal mortality is the groundwork on which life-saving campaigns must be built.

THE SERUM CAROTENE IN DIABETIC PATIENTS

WITH CLINICAL EVIDENCE OF CAROTENEMIA AS DETERMINED BY THE PHOTO-ELECTRIC COLORIMETER

GEORGE H. STUECK, M.D.
GERALD FLAUM, M.D.
AND
ELAINE P. RALLI, M.D.
NEW YORK

In a previous study¹ the average fasting serum carotene in normal persons estimated by the White and Gordon method² was reported as 0.109 mg. per hundred cubic centimeters. In diabetic patients the average was 0.262 mg. per hundred cubic centimeters. In the present study all the diabetic patients had clinical evidence of carotenemia, as shown by pigmentation of the palms of the hands, soles of the feet or subconjunctival fat. The blood was taken three hours after the break-

fast meal. We have found that the serum carotene does not rise after a meal unless a significant amount of carotene is taken with the meal.³

The extraction of the serum was carried out as described by White and Gordon² with 5 cc. of serum. The petroleum ether was removed from the alcoholic ether phases and a few more cubic centimeters of petroleum ether added. After the mixture was shaken and allowed to separate, the petroleum ether was removed and the procedure repeated until all other soluble material had been extracted. The ether was

then made up to a volume of from 10 to 20 cc, depending on the intensity of color. The extracted carotene was read in a photo-electric colorimeter.⁴ A blue Jena glass filter BG 12 with a maximum transmission at approximately 425 millimicrons was used, as this was nearest to the maximum absorption band of carotene.

Curve showing concentration of crystalline carotene against the percentage of absorption of light

Calibration curves done with crystalline carotene (S. M. A.) both in petroleum ether (boiling point from 40 to 60 C) and cyclohexane (boiling point 81 C), showed the extinction values to be the same in the two solvents (table 1). Cyclohexane is superior as a solvent because of its slower rate of evaporation. The

13	0.210	0.210

accompanying chart is a plot of the concentration of crystalline carotene against the percentage of absorption of light.

In table 2 is summarized the serum carotene together with the age, sex, duration of diabetes, diet and insulin requirement for each patient. In every case carrots

made up a large part of the vegetable component of the diet, some patients using carrots as often as twice a day, others using them four or five times a week. The lowest serum carotene in this group was 0.210 mg per hundred cubic centimeters. In six of the thirteen cases the serum carotene was above 0.312 mg. The higher level of serum carotene in this group as compared to the group originally studied is consistent with the results of clinical evidence of clinical carotenemia.

In view of the fact that in the earlier study the extracted carotene had been read in a colorimeter against dichromate standards, determinations were made on some of the serums by this method and in the photo-electric colorimeter (table 3). These results show a fair approximation within the ranges determined. We have found the method now used accurate to within 5 per cent.

SUMMARY

1 The serum carotene was determined in thirteen diabetic patients with clinical evidence of carotenemia.

2 The serum carotene was above the normal in all the patients. The average serum carotene for the group was 0.392 mg, which was higher than in the previously reported group of diabetic patients.

3 The higher level of serum carotene is consistent with the appearance of clinical carotenemia.

4 The photo-electric colorimeter is a convenient and accurate method for the determination of carotene.

BENZEDRINE SULFATE AND ATROPINE IN TREATMENT OF CHRONIC ENCEPHALITIS

ISIDORE FINKELMAN, M.D.

CHICAGO

AND

LOUIS B. SHAPIRO, M.D.

ELGIN, ILL.

Atropine and related drugs (scopolamine, stramonium) have proved their value in the symptomatic treatment of chronic encephalitis. There is a definite decrease in rigidity and tremor as well as a decrease in sialorrhea. However, there are annoying symptoms in this disease which are not affected by atropine. These are oculogyric crises, drowsiness during the day and sometimes also wakefulness at night. Some patients also have a feeling of exhaustion.

Benzedrine sulfate has been used with success in sleep disorders (narcolepsy).¹ It has been found helpful in certain conditions characterized by fatigue and depression² and it has been reported as being of some symptomatic value in chronic encephalitis.³

Some of the symptoms of chronic encephalitis are due to parasympathetic stimulation.⁴ The addition of benzedrine sulfate, which is a sympathomimetic drug, to the

atropine treatment should enhance the effect of the latter. It has already been established that atropine when combined with benzedrine sulfate markedly increases its effect.⁵

Observations were made on twelve patients with chronic encephalitis. Before we began this study, eleven of the patients were on treatment with atropine sulfate, from 10 to 15 drops of 0.5 per cent solution three times a day. One was treated with scopolamine hydrobromide, $\frac{1}{400}$ gram (0.00065 Gm) three times a day. Benzedrine sulfate was then added to the treatment, the dosage ranging from 20 to 30 mg a day, one half of the dose being given at 7 a. m. and the other half at noon. After several days, ten of the patients complained of dizziness, precordial distress and palpitation. The second dose was discontinued in these patients. Two patients were continued on the full dosage, one receiving 30 mg and the other 20 mg a day—in addition to atropine—without any untoward effects. This treatment was discontinued after a month, and benzedrine sulfate alone administered, 20 mg a day. We were able to carry out this treatment for only seven days because all the patients complained bitterly about this form of therapy and they were definitely not benefited. The tremor increased. The patients were more helpless, could not feed themselves and had a greater tendency to fall. During the following thirty days atropine alone was administered. After this period the patients were again placed on atropine and benzedrine sulfate as in the first month of the experiment. The patients have been on the atropine plus benzedrine sulfate treatment uninterruptedly for varying lengths of time—none less than a month and three for eight months.

TOXIC EFFECTS

During the time that we were interested in this form of treatment there was an epidemic of influenza and two of the patients under treatment died with clinical evidence of pneumonia. We could not find any causal relationship of the death to the administration of benzedrine sulfate. However, stimulation of the sympathetic division of the autonomic nervous system by benzedrine sulfate, the effect of which was enhanced by paralysis of the parasympathetic division by atropine, may have reduced the resistance of these patients to the pneumonic infection. This needs further study. Moreover, these two patients were different from the others clinically in that, although they had signs of parkinsonism, in neither was a history of lethargic encephalitis elicited and both had suffered a skull trauma, one at the onset of the symptoms and the other after the syndrome had been well defined. This would suggest that head trauma with neurologic symptoms may be a contraindication to the administration of benzedrine sulfate. The two cases are included in the case reports (cases 10 and 11).

SYMPTOMATIC EFFECTS OF BENZEDRINE SULFATE AND ATROPINE IN PARKINSONISM

On comparing the observations during treatment with atropine alone, benzedrine sulfate alone and the combined treatment of atropine and benzedrine sulfate, it was evident that the best therapeutic results were obtained with the combined treatment. When benzedrine sulfate and atropine were administered, tremor was diminished in three cases in which atropine alone was unsuccessful. Oculogyric crises disappeared in

two cases and the frequency was diminished in five. The others did not have this symptom. The tendency to sleep during the day and remain awake at night was reversed to normal in all who had this symptom (eight patients). The patients who formerly had to be fed or dressed by the attendant could now dispense with this assistance. All but two of the patients said they had more "energy" or "ambition" than during their previous treatment with atropine alone. In two of the cases there was no greater improvement with the combined treatment than with atropine alone.

SUMMARY

Twelve patients with postencephalitic parkinsonism were treated during consecutive periods with atropine, benzedrine sulfate plus atropine, benzedrine sulfate alone, and again with benzedrine sulfate plus atropine. The best results were obtained during the combined treatment of atropine and benzedrine sulfate. Although atropine alone caused a diminution of tremor and rigidity, the addition of benzedrine sulfate caused improvement in the sleep cycle and reduced the frequency or caused the disappearance of oculogyric crises, and there was a feeling of increased energy. Two of the patients died during an influenza epidemic. Both had a history of head trauma. The relation of increased sympathetic stimulation to a reduction in resistance to pneumonic infection and the contraindication of benzedrine sulfate in patients with head trauma needs further study.

REPORT OF CASES

CASE 3—E. P., a woman aged 35, married, had lethargic encephalitis in 1931. Very soon she developed temper tantrums and paranoid ideas and she mistreated her children. She was admitted to Elgin State Hospital Nov. 15, 1933. There were manifestations of postencephalitic parkinsonism, such as masked facies, ventroflexion of the head and body, marked tremor of the upper extremities and jaw, monotonous speech, cogwheel rigidity and propulsion in gait. This was the only patient on scopolamine treatment. There was no further decrease in rigidity or tremor when benzedrine sulfate was added to the scopolamine treatment, but there was marked improvement in her sleep cycle, a feeling of exhilaration and a noticeable increase in activity.

CASE 4—M. L., a woman aged 20, single, at 12 developed a tremor of the left arm and leg, which became progressively worse, and she had frequent oculogyric crises. Examination revealed a masked facies, tremor of the left arm and leg, cogwheel rigidity and a reversal of the sleep cycle. The patient had a marked improvement in the tremor and sleep cycle with the combined treatment. During the treatment with atropine alone she could not sleep at night and a sedative was necessary. However, on the addition of 10 mg of benzedrine sulfate to the atropine dose, the patient was awake all day and was able to sleep at night without the use of a sedative.

CASE 6—H. H., a man aged 22, admitted to the hospital May 23, 1929, had a coarse tremor of both upper extremities, a marked speech defect, sialorrhea, masked facies and cogwheel rigidity. He was sleepy during the day and awake at night. When treated with atropine and benzedrine sulfate there was a definite improvement in his sleep cycle. He was awake and active all day. The patient said that he felt more "ambitious." There was a slight improvement in his speech.

CASE 7—J. L., a man aged 32, single, had lethargic encephalitis in 1924. He became apathetic and indolent. Examination revealed the typical signs of postencephalitic parkinsonism. He had a masked facies, tremor and cogwheel rigidity. He had had oculogyric crises three times a week. During the oculogyric crises he had obsessive thoughts. His speech was monotonous. When 30 mg of benzedrine sulfate a day was added to the atropine treatment the oculogyric crises disappeared, his activity increased and his speech defect and tremor diminished.

CASE 9—C. B. a man aged 29, admitted to the hospital Dec. 28, 1934 at the age of 14 began to have difficulty in talking and walking and his condition became progressively worse.

⁵ Meyerson, Abraham, Loman, Julius and Dameshek, William. Physiologic Effects of Benzedrine and Its Relationship to Other Drugs Affecting the Autonomic Nervous System. *Am. J. M. Sc.* 192, 560 (Oct) 1936.

Examination showed a masked facies, tremor of the upper extremities, monotonous speech and sialorrhea. He had oculogyric crises about once a week. Atropine treatment caused some improvement in the tremor but did not affect the oculogyric crises. With the combined treatment of atropine and benzedrine sulfate the oculogyric crises became very rare. The patient was now able to dress and eat by himself whereas formerly he required assistance.

CASE 10—S V, a man aged 28, single, admitted to Elgin State Hospital Oct 19, 1935, at 12 struck his head against a post and had several ill defined convulsive seizures. Soon after he became mentally dull and had a masklike facies and needed assistance in bathing, shaving and eating. On examination, it was found that he had a cogwheel rigidity, propulsive gait, masked facies, sialorrhea and tremor of the jaw. There was no improvement on the combined treatment of atropine 10 drops three times a day and benzedrine sulfate 10 mg daily. After a month on treatment he had signs of an upper respiratory infection. The following day there were signs of a right lower lobar pneumonia. The pulse was 132 and temperature 104.8. The atropine and benzedrine sulfate treatment was discontinued. His temperature fell gradually after two days to 99 F but rose gradually again to 104.6. His pulse continued rapid, 112 to 148, and he died six days later.

CASE 11—W G, a Negro aged 27, single was admitted to the hospital May 1, 1931. On examination it was found that he had a masked facies, cogwheel rigidity tremors and loss of associated movements. He was sleepy during the day and had difficulty in sleeping at night. June 5, 1933, he fell and sustained a skull fracture of the left frontal bone. The tremors increased. On the combined treatment of benzedrine sulfate and atropine his tremors lessened, he had more energy and was awake during the day and was able to sleep at night. While on this treatment he developed signs and symptoms of bronchopneumonia. His pulse rose from 90 to 116 and was 120 before death. His temperature ranged between 102 and 104 and he died three days after the onset of the pneumonic involvement.

Clinical Notes, Suggestions and New Instruments

DERMAGRAPH A NEW INSTRUMENT FOR LOCALIZING PAIN

ELIAS LINCOLN STERN M.D. NEW YORK

This instrument enables one to localize accurately and quickly hyperesthetic segments of the body. A freely movable wheel (fig 2) with sharp, closely set, radiating points is mounted at one end of the instrument. This wheel is lightly applied to the skin and then drawn across the area being investigated. The patient will feel pain as it crosses the hyperalgesic areas. When

Fig 1—Appearance of dermagraph

applied parallel to the spine, and about 2 inches (5 cm) from the midline of the back, all the segments from the neck to the sacrum can be quickly tested. A rather constant pressure can easily be maintained along the course of the application.

At the other end of the instrument is a small disk wheel (fig 3), freely movable which has a rather sharp but not a cutting edge. This is used in a similar manner, excepting that

greater pressure is exerted on it as it is drawn over the skin. After a minute or two the skin reaction is observed. In cases of dermatographia a wheal appears almost immediately along

Fig 2—Testing for hypersensitive areas

the track of the application. Over hypersensitive segments, particularly of the sympathetic nerves, a white line flanked by a red streak on each side is noted. The normal reaction consists

Fig 3—Testing skin reaction

of a red line flanked by white lines. The use of this end of the instrument enables one to localize referred pains more accurately and aids in establishing diagnoses in obscure conditions.

From the Department of Sympathetic Neural Surgery, Sydenham Hospital

In addition, the disk wheel can be used to test the superficial reflexes and can be used repeatedly without scratching the patient's skin

It is obvious that the use of this instrument is neater, quicker, and more practical than the use of the usual safety pin or straight pin

1 East Seventy-Ninth Street

PERSISTENT BUCCONASAL MEMBRANE IN THE NEW BORN

H B LEMERE M D BEVERLY HILLS CALIF

This is a report of a case of persistent bucconasal membrane which was relieved permanently by probing and dilation. Cases previously reported in the literature have been in rhinologic journals, which do not usually come to the notice of obstetricians. The opinion expressed in the literature is that a large percentage of these children die of asphyxia without the cause of death being suspected. It is desirable, therefore, that obstetricians be familiar with this possibility. A simple emergency method of probing which gives immediate relief is also outlined. This life-saving procedure has not been given in any previous articles in the literature.

REPORT OF CASE

Baby William W was referred to me Jan 2, 1935, by Dr R C Nelson who gave me the following history. The date of birth was Oct 29, 1934. The mother had three other children. There was difficulty in starting breathing at the time of birth. The child always breathed entirely through the mouth and would become cyanosed when feeding at the breast. After the first few days he nursed from the bottle, attacking the bottle vigorously and then stopping to take breath. He was able to take only 3½ ounces (105 cc) at one feeding. He weighed at birth 7 pounds 3 ounces (3,260 Gm) and ten days later 7 pounds 2 ounces (3,232 Gm). I first saw the child at this time.

On admission the baby appeared well but was breathing entirely through the mouth. On account of the small postnasal space and the strength of the tongue and pharyngeal muscles it was impossible for me to pass my finger into the postnasal space without trauma. The nose and pharynx appeared normal and healthy. A tentative diagnosis of persistent bucconasal membrane was made. Five days later the child was operated on under general anesthesia. A small dull curet was passed along the inferior meatus on the right side and encountered, apparently slightly in front of the posterior nasal choanae, a firm membrane. This was broken through and gave the impression of a thin, firm partition. The back of the curet was used with firm pressure to dilate the opening. Immediately the child closed its mouth and breathed through this nostril. The left side of the nose was then opened and the membrane gave the same resistance. The mucus from the child's nose and throat was bloody but there was no free bleeding. There was no attempt made to bite or scrape away the membrane, only the pressure of the dull curet being used to enlarge the opening. The procedure turned out to be so simple and devoid of trauma or shock that the anesthetic used proved unnecessary. Post-operative progress was uneventful. The baby had gained 7 ounces (200 Gm) five days after the operation and was breathing through the nose and nursing without difficulty. One year later it was learned through the mother that the child was breathing normally.

LITERATURE

All textbooks on the nose and throat that I consulted do not mention this condition. Textbooks on pediatrics occasionally give it a brief paragraph. There are a number of cases reported in the laryngologic literature. Phelps¹ in reporting two cases in 1925 gives a good bibliography which I have used freely in this report. The classification in the literature is usually monolateral and bilateral. Each of these again is divided into partial or complete occlusion and a further differentiation into those cases discovered during infancy and those found later in

life. In 1923 Liberson² stated that 170 cases of all types had been recorded to that date. Cases of congenital, bilateral or complete occlusion are rarely reported, partly because they occur infrequently and partly because many must result in death at birth from asphyxia and remain unrecognized. Otto (1830) first reported a case of congenital occlusion found at autopsy. The first clinical case was reported by Emmert³ in 1853. Fraser⁴ and MacKenty⁵ report adult cases and both give a good summary and bibliography on this condition.

Most writers agree that this is a congenital defect and not due to a pathologic general condition. The theory that it is an outgrowth from the horizontal plate or from the vertical plate of the palate bone or from the vomer has been advanced. Schaeffer describes the development and disappearance of the bucconasal membrane as follows:

"The characteristic epithelium of the nasal areas is recognizable as early as the third week of embryonal life. During the fourth week, these areas become passively depressed by a positive increase in the thickness of the surrounding mesoderm which pushes the overlying ectoderm into relief. The nasal pits are thus formed. In a thirty-five day embryo, the nasal pits have deepened sufficiently to partake of the nature of cleft-like fossae, which end blindly at their dorsal and inferior termination. This is the primitive nasal fossa and its dorsal growth meets the ectoderm of the oral fossa and forms the bucconasal membrane. This membrane is so attenuated in a 35 to 38 mm embryo that rupture usually ensues and the primitive choanae are formed, which establishes the communication between the nasal fossa and the oral cavity and also delineates the primitive palate. Lack of this rupture leads to atresia of the choanae, as a result of an organization of the epithelial plugs which occasionally block the choanae, rarely caseous tissue develops in the organization."

My case might be described as persistent bucconasal membrane. If the condition had persisted to adult life, the median layer of bone would probably have grown to a pronounced bony plate.

DIAGNOSIS AND TREATMENT

The diagnosis of congenital bilateral persistence of the membrane in new-born children is simple. I know of no other condition that can produce complete obstruction to the nose with the exception of a congenital postnasal polyp, a rare condition. A probe can be passed and the membrane detected. A Politzer air bag may be used in either nostril and the impermeability of the nose demonstrated. In some cases the finger can be passed in the posterior pharynx and the membrane palpated. Phelps was able to see the membrane by passing a Holmes nasopharyngoscope into the mouth. Sometimes a new-born child will refuse to breathe at all if the nose is occluded and will die of asphyxia if efforts to force open the mouth or probe the membrane are not immediately undertaken. The treatment in my case was simple. Rupture of the membrane and dilation of the openings was all that was necessary. In a new-born child or very young infant this is probably all that is required or advisable, this membrane being similar in nature to the familiar membranous occlusion of the lacrimal duct, which remains patulous after once being broken through and dilated. All authorities agree that later in life, after the bone in the membrane is developed, it is difficult to maintain an opening, and MacKenty and others advise biting away the posterior portion of the septum as being necessary to maintain an opening. This has led to the opinion that even in infancy an elaborate operation must be performed. In my case the opening remained without a tube or obturator to maintain its permanence. There was no reaction from the procedure. The child breathed through the nose at once, and one year later the report was that breathing was normal.

COMMENT

Persistent bilateral bucconasal membrane producing complete nasal obstruction was relieved by simply rupturing the membrane. New-born children may die of asphyxia if there is complete obstruction to nasal breathing. The instinct of nose

breathing may be so impelling that mouth breathing cannot be accomplished. Others may die of malnutrition from interference with feeding.

It is desirable that obstetricians recognize this condition in case of asphyxia and also know the ease with which rupture of the membrane and dilation of the opening may be accomplished. The pediatrician will be interested in the interference that it caused in nursing. The literature on this subject is comprehensive, and my purpose in reporting an additional case is to show the result of the operation of simple rupture of the membrane. In none of the reports could I find that this simple procedure was performed or advocated. In the new-born it is not desirable to subject the child to the formidable proceedings advocated in the literature, but the probing can be carried out immediately without shock or injury.

THE TRACING OF SYPHILIS THROUGH COMMON AILMENTS

CLINICAL LECTURE AT ATLANTIC CITY SESSION

A BENSON CANNON, M.D.

NEW YORK

A scientist once remarked that after five years' work in a certain field he had "allowed himself to speculate on the subject", after twenty-two years of painstaking research, he writes that it will take him many more years to complete it but that he will now consent to publish a brief abstract (one volume) of his researches. What Darwin wrote concerning the genesis of his "Origin of Species" might well apply to any man who would undertake a comprehensive study of latent syphilis. Like Darwin, I have "allowed myself to speculate on the subject." Unlike Darwin, I am still far from the point where I might presume to publish a 450 page "abstract" of any research I may have made.

If one speaks of clinical latency in syphilis, as is customary, there are many angles from which the subject may be studied. From the vantage point of the group with a large clinical material at its disposal it is possible, for example to study the duration of clinical latency in treated cases as compared with untreated or inadequately treated ones. Such comparisons, even when fragmentary and limited in scope, have in fact served as one of the principal guides in determining what constitutes "adequate" treatment. Likewise, a careful study of the behavior of the Wassermann reaction, taken frequently over long periods of time, in patients who have achieved clinical latency, would contribute much to our understanding of the "Wassermann-fast" case, long a bone of contention among syphilologists.

These methods of approach, in order to function adequately, presuppose a large clinical material observed over long periods and studied in retrospect by a group of specialists with a clerical staff at their disposal for the gathering and correlating of statistical data. The work undertaken along these lines by the Health Organization of the League of Nations and particularly by the Cooperative Clinical Group in this country deserves the highest commendation and should be followed with

interest by every worker in the field. Bruusgaard's unique contribution from the Oslo clinic on the proportion and duration of clinical latency in untreated cases followed for many years is also of interest in this connection.

It is possible, however, to approach this subject from other angles—angles which it seems to me represent the more immediate problems of the general practitioner. The average practitioner of my acquaintance will look with respect on the imposing array of statistics marshaled by some authoritative body of investigators, but privately he is likely to pin one of the investigators down to two or three everyday questions, such as: Just what is a latent case of syphilis? How am I to detect it? and How should I treat it—if at all?

When I am pinned down to a definition of latent syphilis I am strongly tempted to reply, in the words of the farmer, "Thar ain't no sich animal." Any schoolboy knows that the word itself derives from the Latin "latere," to "lie hidden," but the sign that is silent before the novice often shouts aloud to the experienced, and what was invisible yesterday may stand out in startling clarity today, with the aid of improved diagnostic facilities. Furthermore, the patient himself is in a constant state of change, so that the man who qualified as a perfect "latent" case on Wednesday has been known to drop dead on Thursday from a syphilitic heart condition, and syphilitic patients supposedly "cured" who came to autopsy from accidental causes have been found to harbor *Spirochaeta pallida* in their tissues. In the present state of our knowledge the positive serologic reaction is the one unfailing sign of the presence of a syphilitic infection, and to say that an infection is "latent" or "asymptomatic" is merely an admission that the site or sites of its activity are not known at the moment.

The most immediate problem, then, with which the practitioner is confronted, in the presence of a patient with a positive Wassermann reaction but without any of the obvious earmarks of syphilis, is to ferret out hitherto unsuspected sites of activity and to treat them according to his observations with the aim of forestalling if possible, further advances of the parasite. For this reason it seemed to me that a record, though of necessity brief, of the actual experiences of physicians in one large city clinic in discovering and treating cases of so-called latent syphilis might be worth communicating.

First, a few words as to how we proceeded.

The present study was originally conceived as part of a larger one dealing with the accomplishments of arsphenamine in the treatment of syphilis of all stages. For this purpose a systematic record was kept of all adult patients admitted to the department of dermatology from the spring of 1935 to the spring of 1937 whose ultimate diagnosis was syphilis. In the course of this study it became increasingly apparent that a large proportion of the patients so admitted arrived in this department by accident rather than by design, having presented themselves originally for some complaint totally unconnected with syphilis—at least in their own minds and frequently also in the opinion of the admitting physician. The approximately 600 cases of syphilis recorded to date are unselected, then, as regards latency and represent all syphilitic patients who were treated with arsphenamine during any or all of this period. It leaves out of account those who received only intramuscular injections and/or silver arsphenamine.

From the Department of Dermatology, Columbia University College of Physicians and Surgeons.
Read in the General Scientific Meetings at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 8, 1937.

Among the cases under consideration 303, or slightly over half, appeared to be free from any external manifestations of syphilis and gave no history of recent infection. These may tentatively be termed "latent," for purposes of this paper. Among this group there were found to be 135 from whom some history of previous infection was elicited. Only eighty-one could recall a primary sore, and many of these were doubtful, being uncorroborated by darkfield examinations or Wassermann tests. Twenty-two gave histories of rashes or other symptoms strongly suggestive of secondary syphilis but could not recall any primary lesion, while only ten of the 135 gave definite accounts of both primary and secondary manifestations, recognized and treated as such. In fact, the outstanding features of the preliminary case histories of this entire series were, first, the tardy recognition of the disease as such and, second, the inadequacy of the treatment received, forty-one patients reporting either no treatment whatever or only local treatment (salves and the like), cautery, "pills," or "drops by mouth." Nearly half the patients who reported a primary lesion received no specific treatment in this stage.

Of the still larger number of patients (168) hitherto unaware of their syphilitic infection, some discovered it only when another member of the family was found to be infected, others, when a routine blood test was performed on application for a position, a considerable number of cases were caught when the persons in question were about to serve as blood donors, a surprising proportion of women patients were sent in from the antepartum clinic with a positive Wassermann reaction but without any other evidence or history of infection. Worry over possible recent exposure brought a number of men, while a still larger number, both men and women, were found to have positive Wassermann reactions when tested in a routine manner on application to the clinic for some injury or ailment not related to syphilis.

The patients to whom I would invite particular attention are those in whom supposedly latent syphilis created special problems of diagnosis and treatment. These patients, constituting a group of ninety-six¹ men and women deemed profitable for intensive study, had presented themselves at the admitting office with a great variety of complaints, none of which were directly attributable to syphilis. Many of the patients brought letters from other hospitals or from their family physicians, giving diagnoses for the most part merely descriptive and reminiscent of Sganarelle: "Your daughter is dumb, she has lost her speech" "Yes, yes, I know that, but the cause?"

Twenty-one of these patients sought admission to the clinic because of gastro-intestinal disorders, eighteen complained of symptoms referable to the respiratory tract, a like number were admitted for pains in bones, joints and muscles—backache being common among this group, there were nine patients whose urinary symptoms constituted their chief complaint, and seven women with gynecologic ailments. Fourteen cited headaches, nervousness and a "general rundown condition," often accompanied by vague aches and pains not definitely localized. These, together with a small group of miscellaneous disorders constituted the complaints which the admitting physician was called on to evaluate in order that each patient might be sent to the proper department for a more complete examina-

tion. In the majority of instances syphilis did not enter the picture at this stage. The patients were distributed to the departments of internal medicine, urology, ear, nose and throat, the tuberculosis clinic or department of gynecology as the case might be. What happened to them in these departments I believe is worth describing further.

PATIENTS WITH DISORDERS OF THE GASTRO- INTESTINAL TRACT

The majority of patients in the group of twenty-one cases in which there were disorders of the gastro-intestinal tract complained of "stomach trouble," epigastric pain, gas and indigestion being cited more often than nausea and vomiting, only three patients reported vomiting blood, and two additional ones had tarry stools. Two patients described "burning sensations" in the abdomen, sometimes radiating to the back and chest. Some complained of loss of appetite, while in others the appetite was unimpaired. Several had tenderness in the right lower quadrant which had led to a tentative diagnosis of appendicitis. There seemed to be no uniformity in the onset of symptoms, some apparently being unrelated to meals, others occurred after eating and others were relieved by food.

All these patients received a thorough physical examination, and all but two had x-ray examinations of the gastro-intestinal tract, stools and vomitus were examined for occult blood, ova and parasites. Some had test meals and analysis of gastric contents. As a matter of course, patients were questioned as to the relation of their symptoms to constipation or to the ingestion of particular foods. It is interesting to note that in nine of these cases, in spite of the most painstaking search, no definite diagnosis was arrived at. Tentative "impressions" of peptic ulcer had to be revised when x-ray examinations and laboratory tests all gave negative results. In two cases diagnosed as due to "chronic constipation" the patients were relieved of their constipation by diet and petrolatum, but pain and distention from gas still continued. In most of the remaining cases x-ray studies (both serial films and fluoroscopic examinations) were reported as being "suggestive" of duodenal or gastric ulcer though some were admittedly inconclusive or atypical, and in one case (in which no x-ray film was taken) opinion seems to have been divided between "acute gastro-enteritis" and "gastric neurosis."

It was usually at this juncture that the routine Wassermann reaction was reported, and twelve persons of this group of twenty whose histories were completely negative for a syphilitic infection were found to have a positive serologic reaction. The test is always repeated in instances in which there are no symptoms or history of previous infection or treatment, and so it happened that the twelve patients, plus others who had given histories of syphilis in the past, were eventually referred to the department of dermatology for treatment of syphilis. Here signs were frequently noted which had been overlooked in previous examinations because attention had been centered on other conditions—the sluggish pupil, the absent knee jerk, the accentuated second aortic sound, the story of repeated miscarriages—none conclusive in itself but all significant to the syphilologist trained to piece together bits of evidence into their proper sequence.

In patients of this group who admitted that they had had a previous syphilitic infection, the estimated duration of disease ranged from five to eighteen years, with an average of ten years.

¹ Seventy-six clinic cases to which were added twenty private cases presenting similar problem.

All these patients, at various intervals after the diagnosis of syphilis had been established, were started on antisyphilitic therapy, usually beginning with intramuscular injections of mercury or bismuth compounds and continuing with alternating courses of arsphenamine and a heavy metal, according to the requirements of the individual case. Potassium iodide was usually taken by mouth between arsphenamine courses. The effect of antisyphilitic treatment on these various stomach ailments constitutes one of the most interesting chapters in my experience. The bare fact that the patients in this group all showed marked improvement in their stomach symptoms under antisyphilitic treatment, while true, might in itself be misleading. Patients who after examination were adjudged to have gastric or duodenal ulcers were almost invariably placed on special dietary regimens, and it was not always possible to determine how much of the improvement was due to the diet and how much to the treatment for syphilis.

When the records were studied more carefully, however, many interesting features came to light. Some patients admitted on questioning that they had not adhered to the diet prescribed, since they felt so much better anyway after injections for syphilis were started. Some adhered to a prescribed diet and took medicines by mouth for a considerable period, with little or no relief, before antisyphilitic therapy was begun in the dermatology clinic, when symptoms cleared, often after a surprisingly few intravenous or intramuscular injections.

I have already mentioned two cases in which chronic constipation cleared under appropriate diet and petrolatum, without any apparent relief from gas, pain and abdominal distention. Both these patients showed marked improvement after a few injections of arsphenamine, one of the two reporting a recurrence of symptoms after a two months lapse from antisyphilitic therapy, and a clearing of symptoms as treatment was resumed. Seven of the patients admitted for gastro-intestinal complaints were found on later examination to have symptoms of cardiovascular involvement. It is often overlooked that epigastric pain and belching may be due to abdominal syphilitic angina when x-ray examination and gastric analyses are negative.

Three cases are reported here in greater detail.

A woman was transferred from a hospital where the diagnosis of inoperable carcinoma had been made. The patient had marked gastro-intestinal symptoms with a decided secondary anemia and a negative Wassermann reaction of the blood. In the second hospital the diagnosis was changed to that of primary anemia. It was not until after she was given a number of transfusions that it was discovered that her husband had a gumma of the leg with a four plus Wassermann reaction. The patient was cured with arsphenamine and has remained well for twenty-two years. (Private case.)

The second case is fairly typical of the patients who consulted a physician repeatedly for stomach trouble without securing any permanent relief until a hitherto unsuspected syphilis was discovered and treated.

CASE 27—K. F., a Negro, aged 24 was first admitted Aug. 10 1926 with subsequent admissions Sept. 2 1931 Jan. 17 1933 and Feb. 8, 1935. On the first admission he complained of attacks of epigastric pain one and one-half hours after meals for the past three years. He returned three times in the next nine years for recurrence of symptoms.

X-ray examination of the gastro-intestinal tract on the first admission led to a diagnosis of "ulcer of the stomach and possible ulcer of the duodenum." Physical examination was essentially negative in 1931 and 1933, no x-ray examination was made in 1933. X-ray films taken Feb. 19, 1935, showed "no evidence of ulcer previously found." Syphilis was denied by name and symptom. The Wassermann reaction of the blood was \pm and of the spinal fluid was negative on the first admission. Later Wassermann reactions were all positive in varying degrees. The Kahn test was positive. There were no symptoms of syphilis.

Ulcer diet and treatment by mouth brought some improvement but the patient still did not feel very well, the hair fell out badly, and the original symptoms kept recurring. Antisyphilitic therapy was begun March 14, 1935, twenty-one injections of mercury compounds and twenty injections of arsphenamine were given during the next year, treatment was then continued elsewhere for one year. His condition was reported "excellent" after twelve mercury injections. There was no return of stomach symptoms up to April 1, 1937, the date of the last visit. The Wassermann reaction was still weakly positive.

In the third instance a patient was operated on for peptic ulcer, but most of the symptoms continued to recur until antisyphilitic therapy was instituted.

CASE 37—R. G., a Negro, aged 34, admitted Feb. 11, 1934, complained chiefly for four years of gas, abdominal distention, belching, with pain and, more recently, intractable vomiting, later coffee-ground material appeared in the vomitus.

X-ray examination of the abdomen was negative. The guaiac test of the vomitus was $++$ and of the stool was negative. There was no free hydrochloric acid, and total acidity was 0. The diagnosis was bleeding peptic ulcer, with obstruction of the pylorus, probably due to stenosis.

There was a history of a primary lesion in 1918, but no secondaries were recalled. He had been treated by mouth only. On admission the blood Wassermann reaction was positive. Sluggish pupils, systolic murmur and marked sinus arrhythmia were noted.

March 5, 1934 a gastrojejunostomy was followed by temporary improvement, but gas and abdominal pain recurred, even with a special diet, and were still present nearly two years after operation. X-ray examination five months after operation showed the gastrojejunostomy functioning adequately.

Treatment with arsphenamine and bismuth begun Jan. 31, 1936 brought about disappearance of pain and marked improvement in the general condition, there was still some gas. There was a recurrence of symptoms after a lapse from antisyphilitic treatment. The patient was still under observation April 6, 1937.

It should be added that patient 37 had come to the clinic first in 1930, complaining of "gas" so troublesome that it had kept him awake for two nights. He was given a gastric sedative by mouth. A Wassermann test was not made and the patient did not return again until 1934, when the symptoms had reached the stage described. The conditions found at operation confirmed the clinical impression of pyloric stenosis, without, however, disclosing the site of bleeding. There was, in the words of the pathologic report, "a 5 cm area of induration just distal to the pyloric vein, on the posterior wall of the duodenum. No crater was felt. There was considerable edema posteriorly as well as anteriorly, extending into the gastrohepatic omentum. Both above and below the site were a number of large glands which were not quite hard enough for metastases. The liver appeared normal."

This is not the place to enter into a theoretical discussion of syphilis of the gastro-intestinal tract but various investigators have called attention to residual damage from a chronic syphilitic of the stomach, in the form of (1) mechanical obstruction from lesions

strategically situated in pyloric stenosis, and (2) fibrotic changes in the walls of the stomach, resulting in shrinkage and reduction of functional capacity. In the matter of ulcer of the stomach or duodenum, it is usually impossible to distinguish between syphilis with intercurrent ulcer and ulcer due to syphilis, and necropsy evidence from various sources would indicate that the single benign chronic peptic ulcer is no more common in syphilitic than in nonsyphilitic cases. It is pertinent to recall that Eusterman,³ summarizing his experiences at the Mayo Clinic, concludes that "in all cases of syphilis in which a demonstrable gastric lesion is present the condition should be regarded as syphilitic until it is proved otherwise" and that, "in the light of accumulating knowledge, the attitude that a case of gastric syphilis is not proved without histologic or bacteriologic confirmation, or both, is unjustifiable." Seventy-nine per cent of the patients in his series were reported cured or much improved under antisyphilitic treatment.

PATIENTS WITH SYMPTOMS FROM THE RESPIRATORY TRACT AND THE CARDIOVASCULAR SYSTEM

Not a single patient in the group of eighteen with symptoms from the respiratory tract and the cardiovascular system complained outright of "heart trouble." The most common complaints that brought them to the clinic were a chronic cough, associated with symptoms suggestive of tuberculosis, pleurisy, asthma, sore throat, hoarseness and sinus trouble. A few of the clinical diagnoses recorded on the case histories will indicate the impression of the admitting officer and the physicians in the various departments: "chronic upper respiratory infection," "chronic bronchitis and emphysema," "common cold," "bronchial asthma," "pulmonary tuberculosis (?)," "pleurisy, probably pleural tuberculosis," and "chronic laryngitis, cause unknown."

In the majority of these cases the condition was of long standing, in relatively few had it come on within the past year or less. Usually the patient had managed to get along with his cough, pleurisy or asthma until some intercurrent infection, usually a "bad cold," brought on an exacerbation of his symptoms and he became worried about the possibility of tuberculosis. It was common to find that patients had been referred by the admitting physician to the tuberculosis clinic because the preliminary examination disclosed a chronic cough, sometimes with sputum (occasionally blood streaked), night sweats, loss of appetite and weight, pains in the chest and a history of exposure to tuberculosis. In the tuberculosis clinic, x-ray examinations of the chest would show the lung fields to be clear and examinations of sputum for tubercle bacilli would be repeatedly negative. The temperature would be normal, and no definite foundation could be found for a diagnosis of tuberculosis.

Frequently, however, in these patients, physical or x-ray examinations of the chest, or both, would bring to light murmurs and enlargement of the heart or the aorta. If these examinations were followed up by an electrocardiogram, evidence of heart muscle damage was often added to the picture. By this time some of the symptoms originally attributed to disease of the respiratory tract—cough, asthmatic "wheezing," and the like—moved over into the frame of cardiovascular disease. When the patient was questioned more carefully

from this angle, many subsidiary physical changes cropped up that had been ignored or minimized in previous examinations, when attention had been directed toward tuberculosis. By this time the examiner was usually in possession of the routine Wassermann report, or the brief mention of an old syphilitic infection, previously overlooked or dismissed as irrelevant, had come to his attention. The patient would then be sent to the department of dermatology, with the pious hope that antisyphilitic therapy might help him, since nothing else had. (Usually, I might add, it did.)

A similar sequence of events could be traced in cases in which causes other than tuberculosis were originally believed to account for the symptoms. A preliminary diagnosis of "asthma" frequently brought the patient to the allergy clinic, where tests with a long series of allergic substances, including pollens, bacteria and foods, would turn out to be negative or inconclusive. X-ray examination of the sinuses disposed of the provisional diagnosis of "sinusitis" in more than one instance, while in others, in which some clouding was observed, nasal irrigations brought only temporary amelioration of symptoms. Laryngoscopy did not always reveal pathologic changes to account for a patient's hoarseness, whereas one patient who had been treated intensively for a year in another hospital for a supposed tuberculosis of the throat found that his "sore throat" had melted away with three injections of arsphenamine, which he was given on the discovery of a positive Wassermann reaction.

It is not implied for a moment that symptoms such as have been described here were invariably found to be due to syphilis. In some instances tuberculosis or an intercurrent infection was indubitably present, together with syphilis of long standing. The more obvious features of the former masked the presence of the latter.

Nor is it to be understood that the case types selected for special study necessarily represent the total distribution of latent cases among the different departments. Many cases of cardiovascular syphilis and syphilis of the nervous system were detected or at least suspected on admission by virtue of a previous history of infection or treatment, plus some sign caught by an alert examiner who followed up his flair promptly with specific diagnostic procedures. The men assigned to the admitting office are as a rule experienced physicians and probably more alive to the possibilities of syphilis than the average practitioner from the smaller community, where the incidence of syphilis is lower than in a cosmopolitan center like New York, and the number of syphilitic patients who seek medical care is correspondingly smaller. Thus it was felt that cases which had proved puzzling to this relatively syphilis-conscious group of physicians might well offer points of interest and practical value to the average general practitioner.

Examples could be multiplied indefinitely, but summaries will have to be limited to a few.

CASE 14—V W, a Negress aged 37, first admitted Nov. 24, 1933, and readmitted Jan. 13, 1936, complained chiefly of a cold in the chest for six days with cough and some phlegm, chronic cough the past winter, and night sweats and loss of weight over the past two years. She had had occasional sharp pains in the chest for the last seven to eight years. Was it tuberculosis? The patient returned Jan. 13, 1936 with the same symptoms as before but no cough. On the first admission in 1933 physical examination revealed rales at both bases, especially on the right and murmurs both diastolic and systolic over the aortic area. X-ray films of the lungs were negative. Examina-

³ Eusterman, G. B. Gastric Syphilis. Observations Based on Ninety-Three Cases. J. A. M. A. 96: 173 (Jan. 17) 1931.

tion of the sputum and urine was negative. The diagnosis was "common cold" with a suggestion of mitral heart lesion.

There was no history of primary or secondary lesions, but one miscarriage at two months and a positive Wassermann reaction in 1926 had been followed by from eight to ten intravenous injections at Bellevue Hospital. The Wassermann reaction was negative on the first admission here. There were no symptoms of syphilis. In 1936 the Wassermann reaction was positive, there were still no symptoms of syphilis.

In 1933 the patient was treated only for a "common cold." On readmission in 1936 the discovery of the positive Wassermann reaction led to antisyphilitic therapy consisting of a bismuth compound and arsphenamine in alternate courses. The patient was much improved after ten bismuth and eight arsphenamine injections. There were no signs of decompensation.

CASE 19—E M., a Negress, aged 30, admitted Nov. 17, 1934, complained chiefly of asthma and an asthmatic wheeze and chronic cold with cough and sputum which had been present for one and one-half years.

Physical examination revealed that the heart was slightly rapid but otherwise the examination was negative. The blood count showed slight anemia. X-ray films of the sinuses were negative. X-ray examination of the chest Nov. 21, 1934, revealed that the lungs were clear but that there was slight thickening of the right apical pleura and slight tenting of the right dome of the diaphragm. The sputum was negative for tubercle bacilli. The urine was normal. The temperature was normal. The diagnosis was "bronchial asthma" and, later, "chronic pulmonary tuberculosis." There was no history of primary or secondary lesions. The patient had had one miscarriage three years previously, one child had died at 2 or 3 days of age four and one-half years before admission and one child, aged 7 years, was living and apparently well. There had been a positive Wassermann reaction seven years before during the first pregnancy, followed by twelve intravenous and twenty-two intramuscular injections at irregular intervals up to two years before admission. The Wassermann reaction was positive on admission, Nov. 17, 1934. The spinal fluid was negative. There was a slightly accentuated second aortic sound, the right pupil was slightly larger than the left.

Tonics and sedatives were given for several months without noticeable improvement. An X-ray film of the chest, June 20, 1935, showed a shadow which had developed at the right apex since the last film which was probably thickened pleura. The parenchyma was clear. After one injection of a mercury compound, fifteen of a bismuth compound and ten of arsphenamine, August 7, the patient felt better, she had an occasional cough and expectoration but no chills or sweats. The temperature was normal and only a few fine rales were heard over the right upper lobe. After nine more injections of a mercury compound, October 28, she felt much better, she had no cough during the summer and gained several pounds, the lungs were resonant, with no rales. Breathing sounds were harsh about the hilus, and the heart was rapid and regular. X-ray examination of the chest, Nov. 6, 1935, showed that the shadow at the right apex had diminished, a few fibrous streaks remained. X-ray examination of the chest March 9, 1936, showed no change. Jan. 11, 1937, after thirty injections of arsphenamine, fifteen of a bismuth compound and forty-four of a mercury compound she had no complaints except occasional mild colds. She was still under treatment May 11.

CASE 23—F L., a Negro, aged 40, admitted Feb. 19, 1935, complained chiefly of (1) pains in the chest and a dry cough for the past six months, with no sputum, hemoptysis or night sweats and (2) swelling in the neck for the past two weeks, an enlarged supraclavicular node on the right, there had been no preceding infection and no known exposure to tuberculosis. He had lost 12 pounds (5.4 Kg.) in the past month.

Physical examination revealed slightly diminished resonance over both lungs, groans and squeaks throughout the chest but no fine rales. Sputum (chiefly saliva) was negative three times for tubercle bacilli. The blood count was normal. The urine was normal. X-ray examination of the chest, February 23, revealed a round shadow laterally overlying the great vessels and projecting to the right, which could be produced by posterior mediastinal adenopathy, also a small oval shadow at

the level of the right fourth rib which might represent an old minimal tuberculous lesion. The tuberculin test, March 12, showed a red raised wheal. The pathologic report based on the excised supraclavicular node read "typical for tuberculosis."

The diagnosis was (1) pulmonary tuberculosis? (2) tuberculous lymphadenitis of supraclavicular node.

There was a history of a primary (?) lesion fifteen months before, which was treated by cauterization, a mercury compound by mouth and one arsphenamine injection. There had been no secondary manifestations. The Wassermann reaction was positive on admission. There were no symptoms of syphilis.

Antisyphilitic therapy was begun April 1, with alternate courses of a bismuth compound and arsphenamine for one year. The patient felt much improved under treatment, he gained 20 pounds (9 Kg.), and his appetite was good. X-ray examination of the chest March 25, 1937, showed that the mass previously reported had regressed or disappeared. There was a small calcified area in the midzone of the right lung field opposite the hilus. There was no complaint at the last visit except an occasional slight pain in the right scapula. He was still under treatment April 8, 1937.

In case 14, symptoms of long standing were masked by the "cold" and signs suggestive of a mitral heart lesion were minimized in the presence of the negative Wassermann reaction and a history negative for rheumatic fever. A single negative Wassermann reaction, however, in a patient with a history of a syphilitic infection inadequately treated, does not prove that the patient is cured of syphilis. The test should be repeated, preferably after a small provocative injection of arsphenamine, a positive reaction is almost certain to appear in one or more tests taken at intervals of a few days or a week. This patient showed a recurrent positive Wassermann reaction three years later, on her second admission to the clinic. It is to be regretted that three years was lost in treating the infection.

It is impossible here to do more than touch on the problem of differentiating pulmonary syphilis from pulmonary tuberculosis. In the opinion of Stokes² "Fever, productive cough, blood-streaked sputum, gastrointestinal symptoms, weight loss and even night sweats are not impossible in pulmonary syphilis uncomplicated by active tuberculosis." With a positive Wassermann reaction and corroborative signs of syphilis, and sputum repeatedly negative for tubercle bacilli, the presumption is already strongly in favor of syphilis. Interpretation of roentgenograms requires special study, but in general the more definitely circumscribed shadow, fibrous tracts radiating from the main lesion and a preference for the right side point toward syphilis rather than tuberculosis. The clearing of symptoms under antisyphilitic treatment remains, of course, the most convincing argument. In both cases 19 and 23 the clinical improvement was supported by repeated X-ray films showing regression or disappearance of the original shadows as antisyphilitic treatment was continued.

CASE 48—L D., a white woman, aged 38, admitted Dec. 6, 1935, complained chiefly of hoarseness of one year's duration, which had become worse since tonsillectomy six months before admission and very severe in the past four weeks. When laryngoscopy was done Oct. 11, 1935, both vocal cords were found to be obscured by soft fibrous tissue, also a web was present anteriorly between the two sides, both ventricular bands were thickened, there was a tumor mass on the left ventricular band. Pathologic changes were not typical of tuberculosis (no tubercles and no caseation necrosis). Stain failed to show acid fast bacilli. "Chronic hyperplastic connective tissue infiltrated with round cells." X-ray examination of the chest December 17, suggested residual infection in the lungs from childhood, there was no evidence of pulmonary infiltration of recent origin. The diagnosis was "chronic laryngitis, cause

unknown", "impossible to make positive diagnosis from pathologic specimen—cancer ? tuberculosis ? syphilis ?"

The history was completely negative. There were no symptoms. There had been no previous Wassermann test or treatment. The Wassermann reaction was positive, December 13. X-ray films of the heart showed a slight increase in the transverse diameter.

Antisymphilitic therapy was begun December 24. The patient improved under a bismuth compound and still more under arsphenamine. The voice was sometimes entirely normal. Hoarseness then recurred during a four weeks lapse from treatment. After resumption of treatment hoarseness improved but has not disappeared entirely. X-ray examination of the heart, April 20, 1937 showed a definite decrease in the transverse diameter since the last film had been taken. She was still under treatment May 18.

Evidently in syphilis of the larynx, as in syphilis of other structures, the active inflammatory process may show marked regression and disappear under antisymphilitic treatment, but fibrosis and scarring, the sequelae of an active process, will of course remain. The hoarseness of patient 48 responded well to antisymphilitic treatment, only to recur during a four weeks lapse from treatment. Residual effects are still in evidence. Another case of hoarseness in this series (case 56) was found to be due to paralysis of the left vocal cord, there were no signs of tumor or ulceration in the larynx.

CASE 56—A man, aged 39, without a history of syphilis, was found to have a positive Wassermann reaction of the blood and of the spinal fluid, fixed pupils, and a soft systolic murmur but no other demonstrable signs of cardiac involvement. The hoarseness improved under antisymphilitic treatment but did not entirely disappear. Paralysis of one or both vocal cords may be caused by pressure from a thoracic aneurysm, but none was made out in the present instance.

In one patient with a negative history of syphilis but with a positive Wassermann reaction, pleurisy cleared entirely under injections of a bismuth compound and arsphenamine, and asthmatic attacks, recurrent since childhood, had become noticeably less frequent and less severe. In spite of this, a cautious physician decided after an attack of asthma to discontinue arsphenamine until the asthma improved. The pleurisy returned, with hemigirdle radiation to the lumbar spine. A lesion then developed on the vulva suggestive of a primary lesion (darkfield negative, one enlarged inguinal gland) and the patient was given a course of eight arsphenamine injections. The pleurisy disappeared. The lesion on the vulva turned out to be a furuncle.

SYMPTOMS FROM THE URINARY TRACT

Symptoms from the urinary tract brought to the clinic nine of the patients in our selected group of cases. Frequency and nocturia, difficult or painful urination, burning, sprained stream and slight enuresis, dribbling, acute retention, hematuria and pain in the lower part of the back were all represented, and there was one case of paroxysmal hemoglobinuria. Many of these patients gave a history of gonorrhea, this, however, did not account for the major symptoms, which had persisted even in treated cases. Roentgenograms of the genito-urinary tract, with one possible exception, were negative for stone and abnormalities, and cystoscopy did not reveal any tumors of the bladder or urethra. Local changes in the bladder will be described in some of the summaries of cases. With indications negative for stone and new growths the examiner usually weighed the possibilities of a local infection, a generalized infec-

tion, particularly tuberculosis and syphilis, and a cord lesion. In women patients the possibility of pressure symptoms from a uterus enlarged by pregnancy or fibroids was of course taken into consideration. In one case a pessary helped but did not entirely eliminate bladder symptoms. There was no evidence of tuberculosis in any of the patients in this group. Two were adjudged to have evidence of a "neurogenic" bladder, one of these was supported by a positive spinal fluid. All but one responded to antisymphilitic therapy either by marked improvement or by complete disappearance of urinary complaints. A few summaries of cases follow.

CASE 77—H. C. B., a white man, aged 48, admitted Nov. 19, 1936, complained chiefly of day frequency every hour for the past six weeks, it would disappear for one or two days and then recur. There were no other urinary symptoms.

Urinalysis was negative. X-ray examination of the urinary tract revealed no evidence of calculus, the right kidney was slightly enlarged and low in position. There were no other abnormalities. The local physician had sent the patient in with a diagnosis of prostatitis because of a slightly enlarged prostate. The urology department made a diagnosis of bladder hyperirritability of unknown origin.

The history was completely negative for syphilis. The Wassermann reaction was negative three years before, according to the patient. On admission the Wassermann reaction was positive, and again when repeated December 3. The right knee jerks, ankle jerks both on the right and on the left and abdominal reflexes were absent, the cremasteric reflex was hypotonic. The heart was apparently normal and the pupils were normal.

Treatment consisted of injections of a bismuth compound, arsphenamine, a mercury compound and silver arsphenamine in alternating courses. The urinary symptoms disappeared under the first bismuth course and had not recurred to the date of the last visit, May 25, 1937.

CASE 51—A. W. L., a Negro, aged 30, first admitted in 1930, and readmitted Feb. 15, 1935, complained on the first admission of frequency and pain in the lower part of the back and in the left shoulder and knees, he made the same complaint on the second admission.

In 1930, X-ray examination of the urinary tract was negative. X-ray films of the back showed no evidence of arthritis but sacralization of the lowest lumbar vertebra (congenital). Cystoscopy revealed moderate inflammation of the trigon and posterior urethra, with some elevation of the left ureteral orifice. The bladder was otherwise normal. Several specimens of urine showed an occasional red blood cell. On the second admission, in 1935, the urethroscope showed the posterior part of the urethra inflamed and the verumontanum raised. No diagnosis was recorded. The history was negative for syphilis. A 'lump in the groin' had been noticed for three weeks fifteen years before. No treatment had been given. The Wassermann test was not done on the first visit in 1930. The Wassermann reaction was positive on the second admission and three successive tests were also positive. There were no symptoms of syphilis.

Local treatment was given in the urology department, including irrigation of the bladder, and prostatic massage gave no permanent relief. An orthopedic belt for the back helped some but likewise brought about no permanent improvement. The condition cleared gradually under antisymphilitic treatment (a bismuth compound and arsphenamine, later a mercury compound and arsphenamine in alternating courses). The patient was dismissed from the urology department "free from complaints" Jan. 29, 1937. Urine was normal April 1. The patient was still under antisymphilitic treatment April 29.

CASE 56—P. L., a man, aged 39, Chinese, admitted Aug. 3, 1936, complained chiefly of dysuria for two weeks and slowing of the stream for a year and a half. The urology department reported that no genito-urinary pathologic changes were found. There was no history of syphilis. The patient had had gonorrhea five years before. The Wassermann reaction of the blood was positive on admission. The spinal fluid was positive September 18, in both the Wassermann and the colloidal gold

test There were fixed pupils A soft-systolic murmur was heard at the apex, x-ray films of the heart were twice negative The electrocardiogram suggested the presence of some damage to the heart muscle There were no other symptoms of syphilis

No treatment was given in the urology department Bismuth compounds and arsphenamine in alternate courses resulted in disappearance of the urinary complaints The patient was still under treatment May 14, 1937

CASE 24—M T, a white man, aged 35, admitted Jan 25, 1935, complained chiefly of "kidney trouble" He had had pain in the lower part of the back radiating down to the left testicle and thigh for the past two months There had been day frequency for the past week but no nocturia or other urinary symptoms There was some swelling of the left testicle Urinalysis was done three times and was normal The prostate felt normal An x-ray examination of the urinary tract was ordered but the patient did not keep his appointment X-ray examination of the heart revealed no abnormality

There was a history of a primary (?) lesion three years before but no secondaries, no blood test had been made, treatment was local and by mouth only The Wassermann reaction was now positive repeatedly There were no symptoms of syphilis

All complaints disappeared under treatment with alternate courses of a bismuth compound and arsphenamine The patient was still under treatment May 12, 1937

CASE 11—F O B a white man, aged 46, admitted Nov 12, 1935, complained chiefly of sprayed stream and slight enuresis for one and one-half years and acute retention of urine for the past fifteen hours The urine was cloudy The prostate was not enlarged and no prostatic stone was found X-ray examination of the urinary tract showed only a "calcified shadow in the left renal area which should be ruled out as kidney stone" The diagnosis was (1) stricture of the posterior portion of the urethra and (2) a large atonic bladder

A history of syphilis was given with a primary lesion five years before, no secondaries had been noted, no blood tests were made and no treatment was given at that time The Wassermann reaction of the blood and of the spinal fluid was positive The pupils were sluggish and irregular, the right larger than the left There were no other symptoms of syphilis

Treatment consisted of ten injections of a bismuth compound and ten injections of arsphenamine The patient passed urine readily after dilation of the stricture There was no improvement in the bladder symptoms The patient transferred to a private physician for spinal treatment, March 18, 1936

CASE 54—W M M, a white man, aged 50, first admitted Nov 21, 1935, and readmitted April 9, 1936, complained chiefly of swelling of the face and bloody urine on exposure to cold during the past two to two and one half years There was swelling over the malar prominences, also the ear lobes would become red and indurated after exposure to cold, especially cold wind Swellings would rise in about fifteen minutes and remain until the patient became warm again and then disappear in from five to twenty minutes The upper lip was sometimes affected Bloody urine was not constant, it had occurred about four times in the past three years after chilling of the feet the urine would be red for only one urination There was no pain or other urinary symptoms and no ankle edema Examination of the urine was negative for albumin and sugar There were 2 red blood cells and 1 hyaline cast per high power field The diagnosis was paroxysmal hemoglobinuria The history for syphilis was completely negative The patient had had gonorrhea at 18 years of age, which was treated, there had been no signs since The Wassermann reaction was positive on the first admission in 1935 and again positive on readmission in 1936

The pupils were slightly irregular, a prolonged blowing systolic murmur was heard over the aorta, with moderate enlargement of the heart to the left X-ray examination of the heart revealed slight enlargement to the left and diffuse dilatation of the aortic arch

No treatment was given on the first admission in 1935 On the second admission in 1936 the patient presented the same complaints as before, evidently untreated in the meantime After

antisyphilitic treatment of twenty injections of a bismuth compound and thirteen of arsphenamine, the patient was free from complaints No further hematuria was noted There was a little swelling of the ears occasionally after exposure to the wind The urine was normal Jan 28, 1937 The patient lapsed from treatment, February 4

Lesions of the bladder in early syphilis have been fairly well documented in recent years, but comparatively little is known about pathologic processes in the urinary tract in later stages of the disease The large atonic trabeculated bladder resulting from lesions of the spinal cord is amply recognized by urologists, but its clinical symptoms—difficulty in starting the stream, dribbling at the end and slight enuresis—are usually so gradual in onset that they are easily ignored or minimized by the patient and general practitioner Sudden hemorrhages without demonstrable cause have in a few reported cases been traced to gummas of the kidney, but the cases that come to necropsy are rare, and the residual damage left by previously active syphilitic processes are identified as such with difficulty even by experienced pathologists Differentiation of syphilitic from tuberculous processes of the urinary tract during life rests chiefly on collateral evidence of a syphilitic infection and the absence of evidences of tuberculosis plus the therapeutic test Improvement under treatment with preparations of mercury and bismuth is usually considered even more conclusive than under arsphenamine, because of the so-called nonspecific effect of the latter in some cases of proved tuberculosis I feel, however, that in tuberculosis of any organ or structure the reputed "nonspecific" effect of arsphenamine may in effect be a specific one, owing to the coexistence of a syphilitic infection masked by the more obvious signs of tuberculosis and by a temporarily negative Wassermann reaction It has been amply demonstrated that a personal history negative for syphilitic infection and one or two negative Wassermann reactions does not exclude syphilis

PATIENTS WITH GYNECOLOGIC AILMENTS

A considerable number of women who came to the clinic for menstrual disorders and symptoms of chronic inflammation of the pelvic organs obtained much prompter relief from antisyphilitic treatment after discovery of a positive Wassermann reaction than they had had under nonspecific therapy Perhaps the most striking cases were those in which the patients complained of menorrhagia and metrorrhagia, examination in the department of gynecology would lead to a diagnosis of "fibroid uterus" or "cystic mass in the region of the ovary" Operation would be advised and the patient placed on the waiting list for admission to the hospital Meanwhile, on discovery that the routine Wassermann reaction was positive, the patient would be sent to the department of dermatology for antisyphilitic treatment It was surprising to find, in going over large numbers of records, how many of these patients reported such marked relief from symptoms that their names were removed from the operative waiting list

In some of these instances, by the time the patient had had one or two courses of antisyphilitic treatment the examiner in gynecology would find that the "fibroid" or the "cystic mass" originally palpated could no longer be identified In other instances there was marked subjective improvement unconfirmed by a pelvic examination Because relatively few of the reports were considered sufficiently full for my purpose, the majority

were excluded from the group selected for special study. Three of those included are summarized here.

CASE 62—V F, a Negress, aged 34, admitted Sept 10, 1935, complained chiefly of unusually long menstrual periods (occasionally up to two weeks) and pain in the right lower quadrant for the past three months, worse during menstrual periods, polyuria and nocturia (three times) had been present for the past month. Some discharge followed the menstrual periods.

On pelvic examination the uterus was enlarged and slightly tender, the lower midline mass extended half way to the umbilicus. Examination of the heart revealed a systolic murmur at the apex, the second pulmonic sound was stronger than the second aortic and slightly accentuated. There was a history of acute rheumatic fever at 21 years. The diagnosis was uterine fibroids and pelvic inflammatory disease, operation was advised and the patient was put on the waiting list. The history was completely negative for syphilis, she had been married ten years and had had no pregnancies. The Wassermann reaction was now positive. X-ray examination of the heart and fluoroscopy revealed an increase in the transverse diameter in the region of the left ventricle and widening of the ascending aorta with increased pulsation, suggestive of aortitis. The knee jerks were not equal.

May 7, 1936, after eleven injections of a bismuth compound and six of arsphenamine, pains in the right lower quadrant were decreased, the cervix appeared healthy, adnexa were not felt, and the uterus was irregularly enlarged. Four months later, after continued treatment, pains in the right lower quadrant were gone, periods decreased from five-six-seven days to four days, bladder symptoms were gone, the general condition was much improved. The abdomen was normal on palpation but gynecologists found the uterus still somewhat enlarged. Operation was canceled. The patient then became irregular in attendance, receiving only eight bismuth injections in twenty-two weeks, then lapsing for eleven weeks without treatment. She returned with a recurrence of all original symptoms, April 26, 1937.

CASE 46—D M, a Negress, aged 24, admitted Feb 26, 1936, complained chiefly of irregular and profuse menstruation with clots, vaginal discharge, frequency and burning micturition.

Vaginal and cervical smears were negative for gonococci and positive for a fungus. A urethral smear was negative for the gonococcus and faintly positive for a fungus. The Frei reaction was negative. On pelvic examination the adnexa were normal, there was a moderate mucoid discharge from the cervix. No diagnosis was reported.

There had been a possible primary lesion ten years before, but no secondaries were recalled. No blood test had been made and no previous treatment had been given. The patient had had gonorrhea one year before. The Wassermann reaction was now positive but there were no symptoms of syphilis.

The vaginal discharge still continued after two months non-specific treatment (hot soda douches, cervix and vaginal canal painted with gentian violet). There were no more complaints after antisyphilitic treatment was started. She received sixteen injections of a mercury compound and nine of arsphenamine. She was still under treatment, March 4, 1937.

CASE 32—B D, a Negress, aged 32, was admitted in August 1934 for panhysterectomy because of uterine fibroids and chronic salpingitis. She returned, October 13, to the department of gynecology for follow up after the recent operation.

The present examination and diagnosis was 'cystic mass protruding into right fornix, probably in Douglas's pouch. Refer for (a second) operation'. There was no history of primary or secondary lesions and no previous blood test or treatment, but there had been five spontaneous miscarriages. The Wassermann test had not been done on admission for the previous operation. No blood test was made until Nov 21, 1935, one year and three months after hysterectomy. The Wassermann reaction was now positive and again when repeated December 4. The pupils were slightly sluggish to light, there were no other symptoms of syphilis.

Antisyphilitic treatment was not started until December 11 or a year and four months after hysterectomy. The patient was under observation in the department of gynecology in the meantime with observations reported as follows. Cystic mass

originally 1 by 2 inches (2.5 by 5 cm) gradually increased to the size of an orange and then to the size of a tennis ball. After fifteen injections of a bismuth compound and nine of arsphenamine, the department of gynecology reported 'No symptoms, pelvis clear, remove name from waiting list'. The patient was still under antisyphilitic treatment May 5, 1937.

PATIENTS WITH MISCELLANEOUS COMPLAINTS

Many subdivisions could be made of symptoms not already classified under one of the major groups, for there is scarcely an ailment known to medical science for which syphilis has not been justly blamed. Innumerable persons who are termed "nuts," "eccentric" or unduly "irritable" by their friends, or labeled "neurasthenics" by their physician, are in reality suffering from some of the more insidious manifestations of syphilis. People who are "anemic," always having one unexplained illness after another, "problem cases," those who complain frequently of headaches, general "run down condition," and vague aches and pains not easily localized, not all, but many of these, are found in the final analysis to have syphilis and respond almost miraculously to antisyphilitic therapy. Conversely, many persons who on a preliminary examination will maintain that they have always been in excellent health, when confronted with a 4+ Wassermann reaction and other significant but hitherto ignored signs of late syphilis, will recall a surprising number of earlier disorders which were in all likelihood manifestations of the disease.

Advanced cases of syphilis of the central nervous system are recognized with comparative ease, but the earlier stages often pass for awkwardness, stupidity or "temper."

In 1923 a well known New York physician sent to my office a man, aged 47, for the removal of a skin cancer on his face. In taking the history I was amazed at the mental slowness and uncertainty of a person with his education and high business attainment (vice president of a large corporation).

Physical examination revealed frank signs of tabes, the Wassermann reaction was 4+ and the spinal fluid very strongly positive, with a paretic curve. He admitted that while in college he had had a penile sore diagnosed as chancroid. The physician who referred him to me was advised of these facts. Nothing further was heard of the patient for about eight months, when he was returned for treatment. There were unmistakable evidences of mental changes in speech, nervousness, depression and inability to concentrate. His general condition improved rapidly for the first few months and then came a complete mental breakdown, with an attempt to murder his wife and two daughters in their sleep. He was put into an institution for about one year and the antisyphilitic treatment was continued. He improved. He was treated for five years continuously and has now been considered cured for six years. Today he is an active efficient business man and has recently married a second time.

A few additional examples are chosen from the many that might be cited if space permitted.

CASE 33—F C, a Negress, aged 24, admitted Oct 18, 1935, complained chiefly of goiter. There was symmetrical but slight thyroid enlargement, polyphagia, increased sweating, choking sensations, loss of weight, exophthalmos, tachycardia, exertional dyspnea, tremor and moist skin.

X-ray films of the chest were negative. The urine showed sugar 4+ on admission. It was normal November 4. The basal metabolic rate was minus 21. The diagnosis was 'fairly definite exophthalmic goiter'. The history was completely negative for syphilis. The Wassermann reaction was positive October 19. There were no symptoms of syphilis.

There was marked improvement of symptoms under antisyphilitic treatment, begun November 21 (ten injections of a mercury compound, ten of arsphenamine and four of a bismuth

compound) Nonspecific therapy was not given. The thyroid clinic, in view of this and the negative metabolic rate, decided that the complaints were "probably not due to the thyroid."

CASE 7—M W, a Negress, aged 33, admitted Oct 1, 1935, complained chiefly of (1) a hard, slightly tender lump in the lower interscapular region, to the left of the midline and of (2) pain in the right upper quadrant radiating to the scapula.

Twice x-ray examination of the chest was negative. X-ray examination of the gallbladder was negative. The urine was normal. The diagnosis was (1) tumor of the interscapular region (cold abscess? myoma? tuberculous abscess of the chest wall? aneurysm? tumor or gumma of the rib?) and (2) cholecystitis. There was a history of a primary lesion in 1927 followed by secondaries. The Wassermann reaction was positive in 1930. Thirty-five intravenous and four intramuscular injections were given, the last in 1929. The Wassermann reaction was now positive but there were no symptoms of syphilis.

The "tumor" diminished in size after three injections of a mercury compound and disappeared completely, as did the pain in the right upper quadrant after four injections of a mercury compound and iodides for four weeks.

CASE 66—R R, a white man, aged 37, admitted Dec 26, 1935, complained chiefly of swollen and painful joints and six months previously of pain and swelling in the right nipple region. The original swelling had subsided, leaving a firm, non-tender lump. Similar lumps were now in the right sterno-clavicular, right humeroclavicular, right acromioclavicular, right fifth rib and left sixth rib. Enlarged inguinal and cervical glands were noted.

The local physician's diagnosis was generalized adenomas and multiple hyperostoses, blood dyscrasia was suspected, but no blood work was done. At the clinic, x-ray films of the chest showed the lungs clear. X-ray films of the bones showed at the outer end of the clavicle evidence of bone destruction and trabeculae in cyst formation. Along the margins of the clavicle at both ends were areas suggesting periostitis. The urine was normal. Blood chemistry was essentially negative. The diagnosis at the clinic was multiple tumors of the ribs, clavicle and scapula, and periosteal fibromas. The question was whether the lumps were gummas or tuberculosis.

The history was completely negative for syphilis. The patient had had gonorrhea fourteen years before. The father had died of syphilis. The Wassermann reaction was now positive. There were no other symptoms.

Alternate courses of a bismuth compound and arsphenamine were given. The lumps diminished markedly after two injections of a bismuth compound. All evidences of syphilis were gone by Feb 21, 1936, after six injections of a bismuth compound and two of arsphenamine. There were no recurrences to May 21, 1937.

CASE 67—G D, a Negress, aged 36, admitted Jan 2 1936, complained chiefly of continuous pain in the throat and left jaw, which later extended to the left ear. There was also tenderness to pressure and some pain on motion at times. Pain later extended back of the ear.

Examination of the ear, nose and throat January 6 revealed nothing to account for the pain, there was slight swelling of the lymphoid follicle low in the tonsillar fossa. The temperature was 99 F. Examination was repeated Feb 3, 1936, with the same results. No diagnosis was made at this time. There was no history of syphilis. The patient was married at 19 and was never pregnant. The Wassermann reaction was negative at the Vanderbilt Clinic in 1929 when the patient had a tonsillectomy, but the patient stated that she had "some injections" elsewhere in 1927. The Wassermann reaction was now positive, but there were no other symptoms of syphilis. The final diagnosis was syphilitic arthritis of the left mandibular articulation.

There was no relief after six weeks of nonspecific treatment. Pain was gone by May 21, 1936 after five diathermy treatments, four injections of arsphenamine, four of silver arsphenamine and three of a bismuth compound.

CASE 70—M L, a Negress, aged 43, admitted June 27, 1936, complained chiefly of pain in the left upper arm with limitation of motion for from two to three weeks, and hard swellings on the forearms for six years, many were hard, movable non-

tender subcutaneous tumors over both arms, some were intimately connected with but not attached to the bones. One on the right forearm looked like an exostosis. The lumps appeared gradually after panhysterectomy at another hospital five years previously. A "lipoma" had been excised from the upper arm at Sydenham Hospital, July 20, 1934.

X-ray examination of the arms revealed "no bony abnormality except a little calcification of a spotted nature overlying the greater tuberosity of the left humerus, which may represent calcification in the subdeltoid bursa." The blood count was normal. The urine showed albumin +, sugar 0.

The diagnosis was brachial neuritis, multiple fibromatosis of the upper extremities and exostosis of the right ulna. The patient stated that she had had no primary lesion. She had had a generalized rash and sore throat "in her twenties." The Wassermann reaction was now positive. The knee jerks were very sluggish, the left being stronger than the right.

July 13, 1936, after one injection of a bismuth compound, the swellings seemed a trifle softer, the patient was sure that they were smaller. October 26, after ten injections of a bismuth compound, she felt well, the swellings in the arms had disappeared, there were no more complaints of brachial neuritis. The patient was still under treatment, May 10, 1937.

CASE 74—M F, a Negress, aged 29, admitted in January 1936, complained chiefly of enlarged, firm glands for one month as follows. Both submental regions were occupied entirely by firm, nodular, movable glandular masses, the cervical, axillary, epitrochlear and inguinal glands were firm and slightly enlarged, there was no pain or tenderness.

X-ray examination of the floor of the mouth revealed no evidence of soft tissue calcification. X-ray films of the chest were negative. X-ray examination of the abdomen revealed nothing definite. Examination of the ear, nose and throat was negative. The diagnosis was tuberculosis (?) blood dyscrasia and Hodgkin's disease (?).

There was no history of syphilis. The Wassermann reaction was now positive.

Bismuth compounds and arsphenamine were given in alternate courses. The glands became smaller after one injection of a bismuth compound. They were still smaller after two more injections of a bismuth compound and "entirely subsided" after five of a bismuth compound and one of arsphenamine. There have been no recurrences to date, May 12, 1937.

One patient sent in by a local physician with a diagnosis of "inguinal hernia" turned out to have a saccular aneurysm of the femoral artery and a positive Wassermann reaction, hitherto undetected. Another patient, suspected of having tuberculosis of the spine, was found to have an aneurysm of the abdominal aorta and a positive serologic reaction. One "subdeltoid bursitis," which had improved very little under physical therapy, cleared entirely after sixteen injections of a bismuth compound and five of arsphenamine, while a woman who had injured her right shoulder in a fall and developed a fusiform swelling in the midportion of the clavicle was finally conceded by her physician to have "a slight touch of lues" which "might account for her periostitis." The gumma was completely absorbed after nine injections of arsphenamine and twelve of a bismuth compound. One patient, symptom free but found to have a high blood and urine sugar, unaffected by a sugar-free diet, saw his diabetes disappear, together with his positive Wassermann reaction, as antisyphilitic treatment was pursued.

Most textbooks duly record the fact that gummas often develop at the site of an injury and that an interstitial keratitis may come on or recur after an injury to the eye. Yet when a woman complains of a blister from a tight shoe that just won't heal, when a boy comes in with a story of eye trouble after being hit in the eye with a baseball bat, when a housewife scalds her hand or when a dancer sprains her knee, to how

many physicians does it occur that the real trouble may be syphilis, either congenital or acquired? The examples cited are not imaginary. They represent actual cases encountered among 300-odd admissions in whom active syphilis was not at first suspected. Not until commonplace injuries failed to heal after weeks or months of treatment by ordinary measures were some of these patients discovered to have a positive Wassermann reaction and some a history of a previous infection, overlooked or passed by as irrelevant to the present complaint. The mystery of the slow healing operative wound—even after the extraction of a tooth—is often solved by the simple procedure of taking a blood test.

THE SIGNIFICANCE OF THE WASSERMANN REACTION

I believe that most physicians agree that a properly controlled, strongly positive Wassermann reaction (with the exception of a few instances such as yaws, acute fever, leprosy and the like) is diagnostic of syphilitic infection. Where many fail to agree is on the clinical significance of the positive Wassermann reaction. I am in agreement with the opinion expressed by Dr. Kolmer that a strongly positive Wassermann reaction is indicative of an active syphilitic process, whether the physician is able to find it or not. Every one is aware of the frequency with which foci of active syphilis are found with a persistent and strongly positive Wassermann reaction. The first place that a physician should look for the seat of infection is in the nervous system (by careful neurologic and spinal fluid examination), and next in the vascular system, notably the heart and large blood vessels, or in the eyes. If these observations are negative and the patient is apparently well, one is apt to minimize the importance of the 4+ Wassermann reaction and tell the patient that there is no evidence of syphilis in his physical examination and that probably syphilis is not a disease for him. There is no method as yet to tell whether or not active syphilitic lesions are affecting other vital parts of the anatomy at that very moment, notably bone marrow, liver, spleen and the smaller blood vessels. It is only in a case of sudden severe damage to some vital organ that one is able to recognize active pathologic lesions in the later stages of syphilis. It would appear to me that all patients with syphilis, as indicated by a four plus Wassermann reaction, are entitled to the benefit of treatment in one form or another.

FIXED REACTIONS

In this connection it might be well to speak of resistantly positive or Wassermann-fast cases. Barring active syphilitic processes of the brain structure, such as interstitial keratitis and congenital syphilis in older children, there is no such thing as a Wassermann-fast case. I have found that asymptomatic Wassermann-fast cases will become negative and remain so if the treatment consists of the best drugs, is continuous, and is persisted in long enough.

TREATMENT OF "LATENT" SYPHILIS

The treatment of latent syphilis is a highly specialized procedure. I have made it a practice to treat all cases of so-called latent syphilis with a strongly positive reaction whether or not there are symptoms. The drugs used, the intervals between treatments and the duration of the treatment depend on the age and the physical condition of the patient. Usually for indi-

viduals who are 45 and under I prescribe continuous treatment with a heavy metal, potassium iodide and arsphenamine for not less than from eighteen to twenty-four months. This is to be followed by a six months rest period during which time the patient takes mixed treatment (a mercury compound and potassium iodide). Then, after a month of rest from mixed treatment, he reports for complete physical examination, blood test and blood count. If his condition permits, he is advised to take mixed treatment for another six months and report. After the third year, he is given a rest of from fifteen to twenty weeks, after which time he receives weekly injections of a bismuth compound. After the fourth year, if there has been no appreciable change in the intensity of the Wassermann reaction, the patient is advised of his status and the suggestion is made that he take three months of mixed treatment or from twelve to fifteen injections of a bismuth compound a year as insurance against a catastrophe of some sort. I do not have the fear of the effects of antisyphilitic treatment that many of my colleagues have in the treatment of late syphilis. I have been amazed at the amount and length of treatment administered to some syphilitic patients without any noticeable detrimental effect.

SUMMARY

The present paper is based on a study of the records of about 300 patients who on admission to the Vanderbilt Clinic in 1935 and 1936, appeared to be free from any external manifestations of syphilis and who gave no history of a recent syphilitic infection. A considerable number of these patients originally came to the clinic for ailments supposedly unconnected with syphilis and were observed and treated in various other departments before being sent to the department of dermatology. A positive Wassermann reaction often constituted the only obvious basis for a diagnosis of syphilis, and in many instances the positive Wassermann reaction was discovered only incidentally, by routine test.

It was found that a surprisingly large proportion of these patients had presented as their chief complaint some ailment commonly encountered in general practice under the names of gastro-intestinal disorders, chronic disorders of the respiratory tract, urinary symptoms, gynecologic ailments and miscellaneous complaints diagnosed variously as neurasthenia, anemia, arthritis, diabetes, hernia, goiter and the like.

The present report attempts to describe, in a selected group of cases, the methods by which other causes were eliminated, and the symptoms were traced to a syphilis hitherto either unsuspected or supposedly inactive.

I have striven to present my material, reported here for the first time, not by analyzing it in retrospect but by following in their natural order the actual experiences of patient and physician through the various steps of diagnosis and treatment. Symptoms which brought patients to the clinic, the diagnostic procedures, including laboratory tests, x-ray examinations and pathologic changes, the evidence for syphilis and the treatment and its results are described as concretely as the limitations of space permit. It is hoped that this approach, by symptoms rather than systems (the usual textbook method), may have proved of considerable interest and some practical value.

371 Park Avenue

The Chemical Laboratory

THE A. M. A. CHEMICAL LABORATORY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Director

EXAMINATION OF CERTAIN AMERICAN BRANDS OF SULFANILAMIDE

The history of the introduction of para-amino-benzene sulfonamide in therapeutics was recounted in THE JOURNAL, January 2

It was apparently first introduced in the United States under the proprietary name "Prontylin." As this product was not, and could not be, protected by letters patent, and as other firms were privileged to make it, the Council on Pharmacy and Chemistry was approached for a nonproprietary name. The announcement of the term "Sulfanilamide" was made in THE JOURNAL, April 17. A report of the Council on Pharmacy and Chemistry on sulfanilamide appeared subsequently in THE JOURNAL, May 29.

A number of firms have submitted brands of sulfanilamide for the Council's consideration with a view to acceptance and inclusion in New and Nonofficial Remedies. The Council in turn asked the A. M. A. Chemical Laboratory to examine the product and elaborate standards for identity and purity. At the time of this report the following firms had presented brands

A method for the determination of sulfanilamide in biologic material, accurately within 2 per cent, has been described recently by Marshall, Emerson and Cutting.¹

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMPLEMENTING THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

SULFANILAMIDE — *p*-amino-benzene sulfonamide — $\text{NH}_2\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$ — The amide of sulfanilic acid

Actions and Uses — Originally it was reported that sulfanilamide acts against Lancefield's group A strains of hemolytic streptococcus by virtue of an apparently specific effect on these organisms. More recent clinical evidence suggests that the action of this chemical may affect other organisms, especially certain gram-negative cocci. The evidence suggests that its action may be antibacterial.

Sulfanilamide has been used primarily in infections due to beta-hemolytic streptococci, especially in the treatment of puer

Characteristics of Various Brands of Sulfanilamide*

Name of Firm	Uniformity of Crystals	Melting Point	Moisture, per Cent	Ash, per Cent	Sulfur, per Cent (Theory 18.6)	Nitrogen, per Cent (Theory 16.3)	Purity, per Cent of Powder	Purity, per Weight of Tablets Containing 5 Grains (0.375 Gm)	Average Weight of Tablets, Gm
Squibb (powder and tablets)	Not uniform not well defined	163	0.4	0.01	18.3	16.2	99.9	0.310	0.415
Merck (powder)	Not uniform not well defined	163	0.4	0.02	18.3	16.4	100.1		
Calco (powder and tablets)	Not uniform not well defined	167	0.4	0.02	18.5	16.3	99.8	0.315	0.465

Parke Davis (tablets)								0.315	0.400

* This includes the brands submitted at the time the report was made are undergoing examination.

Since then other firms have submitted their brands of sulfanilamide which

of sulfanilamide to the Council: the Calco Chemical Company, Inc., Lederle Laboratories, Inc., Eli Lilly & Company, Merck & Company, Inc., Parke, Davis & Company, E. R. Squibb & Sons, and Winthrop Chemical Company, Inc. (under the name of Prontylin). In all cases the product was a white, crystalline substance without perceptible odor and possessing a slightly bitter taste. The index of refraction of the crystalline product was found to be approximately 1.60. For convenience, the analytic data are tabulated.

From the accompanying table it will be noted that the preparations were of approximately the same grade of purity, ranging from 99.5 to 100 per cent. Because of the possibility of harm from the use of such a preparation, it was deemed necessary that the standards should be rigorous and fairly complete. Based in part on the foregoing data and in part on the material supplied by manufacturers, tests and standards have been evolved which appear in this issue in the New and Nonofficial Remedies department under sulfanilamide.

From the structure of the product, it will be noted that it is an "aniline derivative" and as such may not be without the harmful characteristics of aniline in producing a change in the hemoglobin molecule (methemoglobinemia). It also contains a sulfamido group, reports have already appeared in the literature of the occurrence of sulfhemoglobinemia arising from too intensive or too prolonged use.

peral fever, erysipelas, hemolytic streptococcus septicemia, streptococcal sore throat and surgical infections with hemolytic streptococcus. Present studies suggest that the drug may eventually prove useful in meningococcal and possibly in gonococcal infections.

It must be remembered that acidosis sometimes follows the administration of sulfanilamide. It has been suggested that sodium bicarbonate may prove useful in combating the acidosis produced by the drug. Jaundice and urticaria have also been reported as undesirable side effects following the administration of this drug. Magnesium sulfate should not be administered during the course of the treatment because it is thought to increase the danger of acidosis. Certain studies indicate that sulfhemoglobinemia may ensue in some individuals especially after intensive or continued administration of sulfanilamide. There is also a possibility that methemoglobinemia and granulocytopenia may follow such therapy and there have been reports of hemolytic anemia following sulfanilamide administration. It is advisable in any extensive use of sulfanilamide to examine the blood microscopically for evidence of blood cell destruction as well as lowering of the white blood cell count, and to rule out both sulfhemoglobinemia and methemoglobinemia by spectrographic examination of the blood.¹

¹ Marshall E. K., Jr., Emerson Kendall Jr. and Cutting W. C. Para-Aminobenzenesulfonamide J. A. M. A. 108:953 (March 20) 1937.
¹ The determination of sulfanilamide in the blood, urine and spinal fluid is described by Marshall E. K., Jr., Emerson Kendall Jr. and Cutting W. C. Para-Aminobenzenesulfonamide J. A. M. A. 108:953 (March 20) 1937 and Schulek E. and Boldizsar I. Zschr. f. anal. Chem. 108:396 1937.

Dosage—The dosage of sulfanilamide by mouth is calculated on the basis of 1 Gm (15 grains) for each 20 pounds (9 Kg) of body weight up to 100 pounds (45 Kg). Apparently 5 Gm (75 grains) represents the maximum daily dose that has been used with safety in adults of average weight. The 5 Gm (75 grains) is divided into four doses given six hours apart. Smaller doses of from 3 to 4 Gm (45 to 60 grains) daily will usually be found sufficient. Although intraspinal and intravenous administration of properly prepared solutions have been used, such use of the drug is largely experimental.

Sulfanilamide occurs as a white practically odorless slightly bitter—with sweet after taste—crystalline substance. It is soluble in hot water, hot alcohol and cold acetone, slightly soluble in cold water and cold alcohol and insoluble in ether, benzene and chloroform. The melting point is 165.166.5°C when a standardized micro-melting point apparatus is used. (This method is preferred for purposes of identification.) The melting point when determined according to the U.S.P. XI method is not less than 165 nor more than 167°C. An aqueous solution of sulfanilamide is neutral to litmus.

Crystallographic analysis of sulfanilamide gave an index of refraction of approximately 1.60.

Dissolve about 1.5 Gm of sulfanilamide in 75 cc of hot water, cool and filter. To 25 cc of the filtrate add 5 drops of nitric acid, 1 cc of silver nitrate T.S. No turbidity should be produced (*halogen ion*). Evaporate another 25 cc of the filtrate to approximately 10 cc and add 0.5 cc of 1 normal hydrochloric acid and 1 cc of barium chloride T.S. No turbidity should be produced (*sulfate ion*). To 0.05 Gm of sulfanilamide add 1 cc of 10 per cent sodium hydroxide and boil gently. Place a wetted piece of red litmus paper over the test tube; no bluing is noticeable (*free ammonia*). Incinerate about 0.1 Gm of sulfanilamide; the residue is not more than 0.05 per cent. Sulfanilamide shall also pass the test for arsenic and heavy metals (U.S.P. XI method). Dry about 0.1 Gm of sulfanilamide accurately weighed to constant weight at 100°C under vacuum not exceeding 150 mm of mercury for approximately five hours; the loss does not exceed 1 per cent.

Place approximately 0.01 Gm of sulfanilamide in a small test tube and heat over an open flame until the material melts; an intense violet blue color develops and an odor of aniline and ammonia is evolved if heating is prolonged. Dissolve 0.01 Gm of sulfanilamide in 0.5 cc of concentrated sulfuric acid; the solution remains clear and colorless on heating to 100°C (*carbonizable impurities*). Add 0.05 Gm of sulfanilamide to 2 cc of 10 per cent hydrochloric acid and boil gently for about two minutes; cool in ice bath and add 2 cc of 1 per cent sodium nitrite solution. Dilute with water to 4 cc and keep mixture in the ice bath for at least five minutes. To 2 cc of this cooled solution add a solution of 0.02 Gm of beta-naphthol in 1 cc of 10 per cent sodium hydroxide; an orange precipitate forms. Dissolve approximately 0.07 Gm accurately weighed of sulfanilamide previously dried in 1 cc of concentrated hydrochloric acid and 5 cc of water. Cool to 15°C and add 15 Gm of ice. Agitate the solution with a small glass rod and titrate very slowly with 0.1 normal sodium nitrite solution. Streak the solution on freshly prepared starch iodide paper until an immediate blue streak is obtained. Each cubic centimeter corresponds to 0.0172 Gm of sulfanilamide. The sulfanilamide assay is not less than 99 per cent nor more than 100.5 per cent. Dissolve 0.015 Gm of sulfanilamide accurately weighed in a small erlenmeyer flask with 3 cc of distilled water, add 0.05 Gm of potassium permanganate and 0.05 Gm of potassium hydroxide. Reflux this mixture for thirty-five minutes. Cautiously acidify with 5 cc of concentrated hydrochloric acid and boil until clear. Dilute with water and add 0.05 Gm of barium chloride pulverized. Filter the solution through a micro-Neubauer platinum crucible; the amount of sulfur is not less than 18.3 per cent nor more than 18.9 per cent.

For assaying sulfanilamide tablets, 5 grains, titrate the dissolved tablets in ice-cold hydrochloric acid solution with 0.1 normal sodium nitrite according to the assay for sulfanilamide. The sulfanilamide found is not less than 0.300 Gm nor more than 0.35 Gm.

Note—For purposes of scientific investigation and identification both diazotization and sulfur assays are given for manufacturing control; either one of these in association with the other tests may be considered adequate.

Sulfanilamide-Calco—A brand of sulfanilamide-N N R.

Manufactured by the Calco Chemical Co. Inc. Bound Brook, N. J.
No U.S. Patent or trademark.
Sulfanilamide Tablets 5 grains.

Sulfanilamide-Lederle—A brand of sulfanilamide-N N R.

Manufactured by the Lederle Laboratories Inc. Pearl River, N. Y.
No U.S. Patent or trademark.
Sulfanilamide Tablets 5 grains.

Sulfanilamide-Merck—A brand of sulfanilamide-N N R.

Manufactured by Merck & Co. Inc. Rahway, N. J. No U.S. patent or trademark.
Sulfanilamide Tablets 5 grains.

Sulfanilamide-Squibb—A brand of sulfanilamide-N N R.

Manufactured by E. R. Squibb & Sons, New York. No U.S. patent or trademark.
Sulfanilamide Tablets 5 grains.

CEBIONE (See New and Nonofficial Remedies, 1937, p. 457).

The following additional dosage forms have been accepted:

Ampules Cebione Sodium Solution 2.1 cc. Each cubic centimeter represents 0.05 Gm cephone and possesses a vitamin C potency equivalent to 1,000 international units.

Tablets Cebione 0.025 Gm.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary

HEINZ STRAINED BEEF AND LIVER SOUP WITH VEGETABLES

Manufacturer—H. J. Heinz Company, Pittsburgh.

Description—Canned comminuted and strained mixture of potatoes, beef, beef and chicken liver, carrots, celery, tomato puree and salt, requiring only warming for serving, and specially intended for infant feeding.

Manufacture—Beef from which the fat has been removed is cooked until tender and comminuted in a grinder or chopper. Chicken and beef livers are cooked together until tender. The vegetables are cooked together and the juices are retained. Air is excluded as much as possible. A high grade canned tomato pulp is added to the batch just before straining when fresh tomatoes are not obtainable. The ingredients are combined, comminuted and strained, thereby removing coarse fibrous material. Air is excluded by an atmosphere of steam. The mass collects under vacuum in glass-lined tanks and is subjected to high vacuum with gentle agitation to remove any air that may remain, filled into enamel-lined cans, sealed under vacuum, and processed at 116°C for seventy minutes in a rotating retort. The manufacturing process and the sanitary conditions are regulated by the U.S. Meat Inspection Act.

Analysis (submitted by manufacturer)—Moisture 86.9%, total solids 13.1%, ash 1.2%, sodium chloride (NaCl) 0.6%, protein (N × 6.25) 5.1%, fat (ether extract) 1.0%, crude fiber 0.2%, total sugar as invert sugar 1.0%, reducing sugar 0.9%, carbohydrates other than crude fiber (by difference) 5.6%, calcium (Ca) 0.025%, phosphorus (P) 0.019%, iron (Fe) 0.0018%, copper (Cu) 0.00029%.

Calories—0.52 per gram, 15 per ounce.

Vitamin—2,000 International units vitamin A per ounce (excellent source), 15 Sherman or 7.5 International units vitamin B₁ per ounce (good source), 42 International units vitamin C per ounce (good source), 25 Sherman-Bourquin units vitamin G per ounce (good source).

(1) HONEY GROVE BRAND CRYSTAL WHITE SYRUP

(2) HONEY GROVE BRAND GOLDEN SYRUP

Distributor—White Villa Grocers, Inc., Cincinnati.

Packer—Union Starch and Refining Company, Granite City, Ill.

Description—(1) A table syrup, corn syrup sweetened with sucrose flavored with vanilla extract—the same as Pennant Crystal White Syrup (THE JOURNAL, Jan. 30, 1932, p. 403).

(2) A table syrup, corn syrup flavored with refiners' syrup—the same as Pennant Golden Table Syrup (THE JOURNAL, Jan. 30, 1932, p. 403).

Claims of Manufacturer—For table use and as a carbohydrate supplement for milk modification in infant feeding.

PHYLLIS XXXXX BRAND EVAPORATED MILK

Distributor—Zimmermann Brothers, Lock Haven, Pa.

Packer—Page Milk Company, Merrill, Wis.

Description—Canned unsweetened, evaporated milk, the same as Page Evaporated Milk Sterilized Unsweetened (THE JOURNAL, May 30, 1931, p. 1872).

G & B BRAND PINEAPPLE JUICE

Distributor—Goldfine & Brenner, Inc., Philadelphia.

Packer—Hawaiian Pineapple Company, San Francisco.

Description—Canned unsweetened pineapple juice, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweated) (THE JOURNAL, June 3, 1933, p. 1769).

REGIONAL ILEITIS

The rather vague term "benign granuloma of the intestine" included in the past a variety of chronic inflammatory lesions which, while resembling grossly new formations, were neither neoplastic nor due to any specific organism. The exhaustive review of literature by Tietze¹ in 1920 and later reports by Moschcowitz and Wilensky² and by Mock³ served to revive interest in the subject without, however, contributing new concepts. In 1932 Crohn⁴ and his associates presented for consideration a definite pathologic and clinical entity which they term "regional ileitis." This new concept was based on a clinical study of fourteen cases and a study of pathologic alterations seen in thirteen resected specimens. The lesion described involved the last 25 to 35 centimeters of the ileum, terminating abruptly at the ileocecal valve. The involved segment is greatly thickened, heavy and reddened. The lumen of the bowel is irregularly distorted and narrowed. The intestinal mucous membrane is subject to a destructive ulcerative process, the existing edema imparting to it a bulbous or cobblestone appearance. The submucosal and muscular layers show inflammatory, hyperplastic or exudative changes. The mesentery of the involved segment is stiff and enormously thickened, and it contains enlarged lymph nodes. Adhesion of the involved bowel to the neighboring viscera, with a slow perforation into these of the ulcerating areas, resulting in the formation of fistulous tracts, constituted a constant and characteristic feature of the disease. In order of frequency, the most common place of adherence was to the sigmoid, another coil of ileum, the cecum, the ascending colon, the hepatic flexure and the parietal abdominal wall.

Microscopic examination revealed various stages of acute, subacute and chronic inflammatory changes. The occasional finding of giant cells was interpreted by

the authors as a foreign body reaction provoked by the inclusion of small particles of vegetable matter. Evidence of tuberculosis, syphilis, actinomycosis, Hodgkin's disease or lymphosarcoma was not found. Inoculation of guinea-pigs, rabbits and chickens with triturated material from mesenteric glands and from the intestinal wall proved negative for tuberculosis. None of the cases presented any evidence of pulmonary tuberculosis and there were no positive Wassermann reactions.

The etiology of this apparently definite clinical entity is obscure. The disease occurs predominantly in young adults and is at least twice as frequent in males as in females. The clinical picture resembles closely that of chronic, nonspecific, ulcerative colitis. The onset may be sudden, with abdominal pain and diarrhea, which are not particularly severe and which tend to recur. The dull, cramplike pain may involve all the lower part of the abdomen but is commonly localized in the right lower quadrant. Weakness, progressive loss of weight and a moderate degree of anemia are significant symptoms. The stools contain mucus, pus and streaks of blood. The white blood count, as a rule, is normal or slightly elevated. The physical signs are those of a moderate sized, firm, tender mass in the right lower quadrant, the presence of fistulas, the scar of a previous appendectomy, emaciation, anemia and signs of intestinal obstruction.

Obviously the pain and tenderness and the mass in the right lower quadrant may give rise to the diagnosis of appendicitis. In half of the cases reported by Crohn the appendix had been removed at a previous operation. The authors are emphatic in stating that the process never transcends the limit of Bauhin's valve and that the appendix was not the cause of the underlying pathologic conditions. The appendix may be secondarily involved in inflammatory alterations, but its mucosa did not give any evidence of inflammation.

Regional ileitis must be differentiated from all conditions characterized by a mass in the right iliac region with diarrhea and fever. These include nonspecific ulcerative colitis, ileocecal tuberculosis, mesenteric tuberculosis, Hodgkin's disease, lymphosarcoma and actinomycosis. Consideration of the history and the physical signs, aided by a careful roentgenologic study of the intestinal tract with the aid of a progress meal, may enable one to make a correct preoperative diagnosis.

The treatment is essentially surgical, its aim being the removal of the involved segment of the bowel. This is accomplished in early and uncomplicated cases by a one-stage resection, while multiple-stage procedures become necessary in the presence of obstruction, fistulous tracts or abscesses.

In 1935 Mixer⁵ reported eleven cases of regional ileitis. The clinical and pathologic features of his cases were identical with those previously reported.

1 Tietze A. Ueber entzündliche Dickdarmgeschwülste. *Ergebn d. Chir. u. Orthop.* 12: 23A, 1920. 9: 219, 1913.
2 Moschcowitz Eln. and Wilensky A. O. Nonspecific Granulomata of the Intestine. *Am. J. M. Sc.* 166: 48 (July) 1923.
3 Mock H. E. *Surg. Gynec. & Obst.* 52: 672 (March) 1931.
4 Crohn B. B. Ginzburg Leon and Oppenheimer G. D. Regional Ileitis. *J. A. M. A.* 99: 1325 (Oct. 15) 1932.

5 Mixer C. G. Regional Ileitis. *Ann. Surg.* 102: 674 (Oct.) 1935.

Careful examination by the culture method, by guinea-pig inoculation and by staining reactions failed to demonstrate the tubercle bacillus. With regard to the etiologic rôle of the appendix, Mixer states that in none of their cases in which appendectomy had not been previously performed was there evidence suggestive of primary appendiceal inflammation, though frequently the appendix was enmeshed in the inflammatory mass by periappendicular adhesions.

The number of cases of regional ileitis observed at the Mayo Clinic, according to Pemberton and Brown,⁶ has rapidly increased since Crohn's publication. They were able to report thirty-nine cases in which diagnosis of regional ileitis was established by operation or necropsy.

Regional ileitis, or Crohn's disease, appears therefore to be a well defined clinical entity with a characteristic pathologic picture and obscure etiology.

AMERICAN ORTHOPEDICS—AN AUSTRIAN OPINION

Extraordinary publicity has regularly accompanied the meanderings about the United States of Adolf Lorenz, since the time when he first came to this country to treat the daughter of a Chicago packer. Now Dr. Albert Lorenz, the son of Adolf, gazing the American gift horse directly in the mouth, gives his impression of American orthopedic surgery in a lengthy article¹ from a public address given before the Society of Orthopedic Surgeons of Vienna in June 1936. The article, citing a number of commonplace observations on the treatment of different orthopedic conditions in this country, contains much that is not only erroneous but somewhat acrid in its criticism and judgment of American orthopedic surgery.

Particularly exasperating are his views on the spirit of American orthopedic surgery in general. This he connects with what he is pleased to call the general American mentality, which according to his description is "a product of mass hysteria and mass suggestion, all due to the feminism which governs the country." The American is the follower of herd instinct, he says, and there is not the slightest credit given to individual initiative. His authority for this bizarre and derogatory standpoint is Sinclair Lewis's "Arrowsmith," although it must have been poorly read and still less understood to omit all the commendatory features of our profession which even this severe critic of medical practice was willing to concede.

He lets himself go particularly in the field of sacro-iliac disturbances. Ignoring the development of diagnostic progress in this field, which has produced a great and laborious literature, principally of American and Italian origin, he considers low back pain an almost

entirely hysterical phenomenon, ridiculing the evidence of osteo-arthritis, sacralization and all those established pathologic appearances which more serious and worth while observers and investigators of both hemispheres have developed. Lorenz classifies all these as hysterical and then indulges in some reflections on American hysteria in general. Another choice morsel is the attitude which he attributes to the American orthopedist regarding operations. He says that the evident zest for new things which controls the profession is the reason why both physicians and patients are eager to try out a new operation. "A patient would be considered unmodern and un-American," he says, "if he would not willingly submit to a new operation."

Lorenz talks about Christian science and finally the chiropractors and the osteopaths. The reason why they make such inroads in the American medical practice is, according to him, that the orthopedic surgeon disdains conservative measures and wants only to apply the knife, therefore the public in search for more sane methods turns to the services of the chiropractors and the osteopaths. He considers both vocations a form of quackery whose practitioners are adept in the correction of fractures and adhesions, and he says that they obtain cures by effecting correction of contractures. He is peculiarly confused about the difference between chiropractors and osteopaths, but he says "in all orthopedic conditions suitable for massage and redressement the chiropractors are successful."

His observations on joint tuberculosis and the general attitude toward the treatment of tuberculosis are less than half truths because he misses that great contingent of orthopedic surgeons who have either retreated from prevailing surgical points of view or have never adopted them. Another strange assertion is that congenital spastic paralysis has something to do with the tendency of obstetricians to accelerate delivery. The same, he maintains, is true of Erb's palsy or obstetric paralysis. Equally startling is his remark that the bloodless reduction of the congenitally dislocated hip is considered here almost "mistreatment." No one knows where this author got his information, as he seems to ignore the great majority of orthopedic surgeons who consider the bloodless reduction of congenital dislocation of the hip within the proper age limit as the method of choice. Furthermore, in spite of Ridlon's modification and improvement on the Lorenz-Pacci technic, the younger Lorenz accuses American orthopedists of being ignorant of the technic of reduction. Extreme as his ignorance is in this particular field, it is still more blatant in the field of congenital clubfoot. The author believes that the Lorenz redressement would here celebrate its greatest triumph because he is under the impression that no American orthopedic surgeon is capable of doing a bloodless correction. Evidently he has never heard of Kite's treatment of clubfoot, or that of many others, nor seen the splendid results that are

⁶ Pemberton J deJ and Brown P H W. Regional Ileitis. *Ann Surg* 105: 855 (May) 1937.

¹ Lorenz, Albert. *Europäische und amerikanische Orthopädie*. Wien. *Mon Wehnschr* 50: 527 (April 23) 1937.

obtained by the use of our American plaster-of-paris casts, without the necessity of sending over to Vienna for "alabaster gips"

The space given to this discussion would not be warranted were it not that a reputable European periodical saw fit to publish these lucubrations of a young egoist whose balance—if any—seems to have been overturned by seeing the family cognomen too frequently in the papers

Current Comment

AMERICAN ASSOCIATION FOR HEALTH AND PHYSICAL EDUCATION

A new organization, developed in Detroit in June 1937 during the summer meeting of the National Education Association, replaces two previously existing groups. For many years the National Education Association has had a department of health and physical education with relatively small membership. There has also been a large national organization, the American Physical Education Association, not affiliated with the National Education Association. The American Physical Education Association had grown to be a strong group with a membership in excess of 8,000 members consisting largely of teachers of physical education, athletic coaches and gymnasium instructors, with a sprinkling of classroom teachers and supervisors on whom had been placed the responsibility for teaching health in the schools. The American Physical Education Association held an annual meeting, conducted several regional meetings each year and met in several states with the state education associations, with whom it was frequently affiliated. It published two journals, the *Journal of Health and Physical Education*¹ and the *Research Quarterly*². Because of the existence and the strength of the American Physical Education Association and for other reasons, the department of health and physical education of the National Education Association never became an effective functioning organism. At the meeting of the National Education Association in 1936, favorable action was taken on proposals from the American Physical Education Association to unite with the National Education Association through its department of health and physical education. At the annual meeting of the American Physical Education Association in 1936 the union of the two organizations was ratified and at Detroit in June 1937 it was effected. These developments interest the physician because of their influence on the health of the school child. The new department or association has organized three divisions, one on health, one on physical education and one on recreation. In the division of health a medical section was organized at Detroit. This medical section is intended to serve physicians interested in the health of the school child and includes, of course, school physicians, physicians acting as members of

boards of education, pediatricians and general practitioners whose practice includes school children. The hope was expressed that many physicians would avail themselves of membership in this section. Membership requirements are that a physician shall be a member of his county and state medical societies and of the American Medical Association. Honorary or associate members of county or state associations or the American Medical Association are included where such classifications exist. The only other prerequisite for membership in the section is membership in the National Education Association. The latter membership may be procured by sending \$2 to the National Education Association, 1201 Sixteenth Street N W, Washington, D C, and specifying that the member wishes to be enrolled in the Medical Section, Division of Health, of the American Association for Health and Physical Education—a Department of the National Education Association. Probably additional departmental dues will be fixed in the near future. For further information either the chairman or the secretary of the Medical Section may be addressed. At the organization meeting in Detroit, Dr. Don W. Gudakunst³ was elected chairman of the medical section and Dr. W. W. Bauer⁴ secretary.

ANTIGENICITY OF HORMONES

In a recent analysis of the antigenic functions of certain gonadotropic hormones, Kindermann and Eichbaum¹ of the University of Prague investigated a commercially available gonadotropic substance isolated from human pregnancy urine. Male or female rabbits repeatedly injected with this product went through three stages in the development of an active antihormonic immunity. The first stage was characterized by the formation and liberation into the blood stream of precipitins and complement-deviating antibodies. They reacted in vitro with gonadotropic substance and also with normal human serum proteins. These antibodies, however, in no way neutralized, inhibited or otherwise decreased the gonadotropic functions of gonadotropic substance as determined by the Aschheim-Zondek reaction. The second stage of active immunization was characterized by the formation of biologically active antihormones. Second stage antiserum neutralized gonadotropic substance, as shown by the negative Aschheim-Zondek reaction. In the third stage of active immunity, precipitins and complement-deviating antibodies disappeared from the circulation but were not accompanied by appreciable reduction in the anti-Aschheim-Zondek reaction serum titer. Neither the presence nor the absence of demonstrable precipitins and complement-deviating antibodies, therefore, is significant in the estimation of antihormonic immunity. The authors recognize, however, that this is but a tentative conclusion based on a study of commercially available and presumably impure gonadotropic substance.

¹ The *Journal of Health and Physical Education* is included with active membership at \$2 a year and with professional membership at \$5 a year.

² The *Research Quarterly* is included with professional membership at \$5 a year.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Dr Hughes Named State Health Officer—Dr Coit I Hughes, Phoenix, was recently appointed state superintendent of public health for Arizona to succeed Dr George C Truman Phoenix. Dr Hughes graduated at the University of Louisville School of Medicine in 1909.

Building Program at State Hospital—A building program has been approved at the state hospital in Phoenix which will cost about \$228,000 of which \$93,616 has been appropriated by the PWA, it is reported. Construction of the first unit in the project a women's ward began in June. This one story unit, costing about \$82,311, will be of Spanish design.

ARKANSAS

Opening for Serologist and Medical Director—The Arkansas State Personnel Division announces examinations for the positions of serologist and medical director. For the serologist no applications will be received after August 7 and applicants must be college graduates with a bachelor of arts or bachelor of science degree with courses in zoology biology chemistry and bacteriology postgraduate technical course in serology, two years' experience as laboratory technician and serologist or college graduates with a major in the biological sciences and four years' experience as a laboratory technician. The maximum age is 35 years. The salary is \$1,500 a year. Applications for the position of medical director will not be accepted after August 14. Requirements include graduation from a class A medical school internship in an approved hospital, skill in diagnosis and therapy of communicable diseases supervisory and organizing ability ability as a public speaker and in securing cooperation from local officials and civic groups. The salary is \$3,000 a year and the maximum age 35 years. Both examinations will consist of a formal application accompanied by a thesis covering specified subjects. Those who pass these requirements will be given an oral examination later. Additional information may be obtained from the personnel division, Capitol Building Little Rock Ark.

CALIFORNIA

Survey of Crippled Children—*California and Western Medicine* reports the results of a recent seven months study of 502 crippled children examined in nine diagnostic clinics held in eight counties of the state. Accidents were the causative factors in the present physical condition of 103 patients the condition was congenital in 313 while disease was responsible in 144. In the last group poliomyelitis accounted for the largest number of cases. While the classification of ages runs from 2 years to 20 and over the largest single number eighty-eight, is found in the adolescent period of 14 to 15 years representing 17.5 per cent of the total number examined 11.2 per cent of the total patients were under 6 years of age. Half of them were under 4 years of age, and 8.1 per cent were 18 years or over, suggesting that disease conditions had existed over a period of years or that children who had previously been surgically treated were reporting back for further orthopedic supervision. Of the 502 patients examined, no recommendations were made for fifty, or nearly 10 per cent. The report stated that this does not necessarily mean that no disease condition existed in this group but that no further care was indicated at the time of the examination. Of 556 recommendations made for 452 patients, the report shows that 71.4 per cent were for orthopedic care and 28.6 for nonorthopedic conditions. The largest number in the second group, or 12.6 per cent, were for the services of an ophthalmologist. Almost as many received recommendations of an orthodontic nature as required the services of other specialists. One third of the total orthopedic recommendations or 29.7 per cent was made for surgery representing both orthopedic and plastic surgery while 10 per cent of the total was for continued orthopedic supervision. Almost as many were made for corrective exercises as for appliances. Only 13.1 per cent of the children for whom orthopedic recommendations were made were referred back to the clinic, private physician or hospital previously attended. Almost as many had been under the care of a private physician as of a clinic indicating either that the majority of the children examined were not under medical supervision or that the service required was in a specialized field the report stated. The

fact that recommendations were made for 90 per cent of the patients examined signified not only the important contribution of the diagnostic clinics in meeting the needs of these patients but the necessity of following through the recommendations of the physician so that, in the end, medical care is not only conserved but made more effective, the report said.

DISTRICT OF COLUMBIA

Medical Bills in Congress—H R 7957, introduced by Representative O'Toole, New York, proposes to provide for the licensing of food handlers for the protection of public health. H R 7982 introduced (by request) by Representative Palmisano, Maryland, proposes to regulate the manufacturing dispensing, selling and possession of narcotic drugs in the District of Columbia. The term "physician" is defined by the bill to mean a person authorized by law to practice medicine or osteopathy in the District of Columbia.

IDAHO

Society News—Motion picture films on obstetric subjects and one on clinical administration of oxygen were shown at a meeting of the North Idaho District Medical Society in Moscow, June 16, the films were discussed by Drs Leonard W Brewer and John Harry Einhouse Moscow.

Personal—Dr Ralph M Alley has been placed in charge of the Indian sanatorium at Lapwai where the Nez Perce Indian agency has been moved from Moscow. The headquarters will have supervision over some 2,500 Indians, 1,400 of whom are members of the Nez Perce tribe—Dr Bruce C Budge, Boise, has been appointed a member of the faculty of Boise Junior College, which plans to offer a two year pre-medical course next year it is reported—Dr Jay H McClellan Jefferson Barracks, Mo, has been appointed chief medical officer of the Boise Veterans' Administration Facility. Boise succeeding the late Dr Rinaldo E Baker. Dr Norbert C Trauba has been acting officer—Dr Howard L McMartin Twin Falls has been appointed director of the Twin Falls county health unit succeeding Dr James W Hawkins, who became state health director.

ILLINOIS

Personal—Dr John W H Pollard health commissioner of Evanston for eleven years has resigned effective September 1, on account of ill health—Dr Karl M Beck has been appointed superintendent of the Lake County General Hospital Waukegan he will also serve as county physician and succeeds Dr Charles Lieber who is returning to private practice it is reported.

Wards of Children's Aid Society Undergo Syphilis Tests—Wards of the Illinois Children's Home and Aid Society are being tested for syphilis as a part of the general campaign against venereal diseases carried on throughout the state, it was announced July 11. The tests are being given to 2,000 wards of the society under the direction of Dr Mandel Spivek of the Children's Memorial Hospital. The society has a turnover of about 500 children a year and as new wards are accepted they will be examined. This program is the first of its kind ever carried on by any children's aid organization in the country it was stated. The project will cost between \$3,500 and \$5,000 a year and contributions are being sought to help defray the expense.

Chicago

Course on Traffic Safety—A gift of \$10,000 to expand the police training program of the traffic safety institute at Northwestern University was announced July 6. The fund was given by the Kemper Foundation for Traffic Police Training.

Dr Pusey Honored—Dr and Mrs William Allen Pusey were honored in Elizabethtown Ky, July 13 when a public reception commemorated their fiftieth wedding anniversary. The celebration was held at the Community House which was given to the town by Dr Pusey and his brother, Dr Brown Pusey. Both were born in Elizabethtown. The former is a past President of the American Medical Association.

River Noise Reduced—A telephone system will replace the whistling on river boats used as a warning to bridge tenders in accordance with recent action of the city council. A dispatcher will be stationed at the Outer Link bridge to pass the word when a vessel approaches. As each bridge is silently warned by telephone from the preceding bridge tender the bridges will open without the accompaniment of the usual whistles.

Questionnaires Seek Public Opinion on Tests for Syphilis—One million questionnaires will be sent to persons in Chicago asking whether they would accept confidential blood tests without cost to themselves in the campaign to conquer

sypilis now being conducted on a national basis by the U S Public Health Service. The plan was begun July 24 when more than 250,000 questionnaires were mailed. Two million franked envelopes for the mailing of the questionnaires and the replies have been supplied by the U S Public Health Service. The clerks are furnished by the WPA, the Chicago *Tribune* reported. Another phase of the campaign was being carried on in the federal statistical office in the Merchandise Mart where 2,893 physicians have enrolled thus far in the drive by returning questionnaires asking data on patients with sypilis under their care and observation in the four months period ended June 30 the names of the patient not to be revealed. All statistical material pertinent to the survey will be released through the Chicago Medical Society it was stated.

INDIANA

Fined for Prescribing Cancer Cure—George Byars, illiterate Negro, was fined \$200 in South Bend, June 22, when laboratory analysis showed axle grease to be the principal ingredient in a "cancer cure" he prescribed. According to the Indianapolis *Star*, Byars has posed as a healer for years, treating patients for cancer and other diseases. The investigation was brought about by the St Joseph County Medical Society and the fine imposed is the maximum penalty in Indiana.

New Division of Laboratories at University—Dr Clyde G Culbertson, assistant professor of pathology, Indiana University School of Medicine, and chief of the bacteriologic laboratory of the state board of health Indianapolis has been placed in charge of a newly established division of laboratories at the university medical center. The division was created by consolidation of the central clinical laboratory for the medical center, the research laboratory, the supervision of the laboratories of the state board of health and another to be established as a medicolegal laboratory. Drs John Lynn Arbogast and Albert W Ratcliffe have been appointed assistants to Dr Culbertson.

IOWA

Outbreak of Smallpox—The state department of health reports an outbreak of smallpox in Jasper County. On July 14 an investigation revealed that thirty-seven persons were either ill with smallpox or had recently suffered an attack of the disease. In one family nine children who had never been protected by vaccination contracted the disease while the father and mother, who had been vaccinated many years ago in Holland, escaped. The investigation further revealed that, so far as could be learned, only one among the thirty-seven smallpox patients showed evidence of vaccination, which in this instance had been carried out over fifty years ago.

Upper Des Moines Annual Summer Meeting—The Upper Des Moines Medical Society will hold its summer meeting on West Okoboji Lake, August 5. The all day program will open with a pediatric clinic conducted by Dr Julian D. Boyd, associate professor of pediatrics, State University of Iowa College of Medicine, Iowa City. Following a conference of county society officers of the third district the speakers will be:

Dr Roger L J Kennedy, Rochester Minn. Diseases of the Thyroid Gland in Children
Dr Ralph Bowen, Oklahoma City. Allergy As Seen in General Practice
Dr Frank R Peterson, Iowa City. Management of Rectal and Low Sigmoid Malnignancies
Dr Frederick A Willis, Rochester. Cardiovascular Syphilis

Dr Edward M Myers, Boone, president of the Iowa State Medical Society, will preside as toastmaster at the dinner in the evening and Dr Ewen M MacEwen, dean and professor of anatomy of the college of medicine will be the principal speaker.

KANSAS

New Health Officer—Dr Fred P Helm, health officer of Topeka, has been appointed secretary and executive officer of the Kansas State Board of Health effective July 15 succeeding Dr Earle G Brown who became health officer of Arlington, Va. Dr Helm graduated from the University of Louisville School of Medicine in 1923. He formerly served as health officer of Miami, Okla.

KENTUCKY

State Society Meeting Place Changed—The annual meeting of the Kentucky State Medical Association will be held in Richmond September 13-16, instead of Berea, September 6-9, as at first decided.

Louisville Health Department Expanded—An appropriation of \$75,000 from the federal government has enabled the department of public health of Louisville to expand its

activities in flood rehabilitation and preventive medicine. A district health center has been opened in the eastern part of the city under the direction of Dr John B Hozier, Louisville, and a trailer equipped with a loud speaker and motion picture machine has been purchased for health education purposes. Additions to the staff include Dr Gracie R Rountree, former health officer of Green County, as assistant director of health in charge of venereal disease control, Dr Annie S Veech as director of maternal and child hygiene, and Arthur G Fuller as sanitary engineer.

LOUISIANA

Arsenical Poisoning—Because of recent cases of arsenical poisoning, C L Clay, state chemist, Louisiana State Board of Health has issued a warning to manufacturers of insecticides or other poisonous compounds resembling flour or other food ingredients to color them so that they may not be mistakenly used in the preparation of food. This treatment is required under terms of regulation number 33 of the state's food and drug laws and violations are punishable by fine, imprisonment and destruction of the offending product and will be rigidly prosecuted the warning pointed out.

Graduate Instruction Reorganized at Tulane—Under a program of expansion of graduate medical education, Dr Hiram W Kostmayer, dean and professor of gynecology, Graduate School of Medicine, Tulane University, New Orleans, will henceforth be known as director of graduate medical studies in the school of medicine and Dr Maxwell E Lapham as director of the graduate medical extension division. All graduate medical instruction will be under the general supervision of Dr Kostmayer and under the immediate supervision and direction of the regular officers of administration and facilities of the several departments of the medical school it was reported. This arrangement will afford those who enroll for medical graduate study all the superior advantages in facilities, equipment and talent of the entire medical department of the university. According to the New Orleans *Times Picayune*, graduate degrees in medicine earned in graduate medical study will be conferred through the graduate school of the university, the faculty of which includes several department heads of the school of medicine.

MARYLAND

New Department Heads in Health Office—Dr David H Andrew, formerly health officer of Wythe County, Wytheville, Va., has been appointed director of the bureau of communicable diseases in the Baltimore health department, effective June 28, to succeed Dr Adolph Weinzirl. Dr Andrew graduated at the University of Maryland School of Medicine, Baltimore, in 1931. Recently he received a certificate in public health at the Johns Hopkins School of Hygiene and Public Health. Dr Phineas J Sparer was appointed recently to the newly created full time position of director of the bureau of tuberculosis.

MICHIGAN

Mayor for Twenty-Five Years—Dr Arnold R Miller has been mayor of Harrisville since 1912. He graduated from the Detroit College of Medicine now known as Wayne University School of Medicine, in 1906 and has been practicing in Harrisville since 1911. Harrisville in Alcona County, has a population of about 500.

Personal—Dr James A Dolce, medical inspector of the Glen Head L I, N Y, schools has been named associate field director and health officer of Allegan County, under a fellowship from the Kellogg Foundation. Dr James R Jeffrey Jr, Miami Springs, Fla., has been appointed a member of the staff of Battle Creek Sanitarium, Battle Creek, filling the vacancy in the department of gastro enterology caused by the death of Dr Elmer L Eggleston. Dr Ervin J Brenner, East Jordan, has been appointed health officer of the newly organized Alger-Schoolcraft county health department. Headquarters are in Manistique, with a branch office in Munising.

MINNESOTA

Dr Rosenow Wins Prize—The James E Stacey award of the University of Cincinnati consisting of a gold medal and \$100 was recently bestowed on Dr Edward C Rosenow Sr, Rochester, "because of recent establishment of the fact that certain types of spasmodic disease—such as chronic hiccup, torticollis and other types of spasm involving particularly the respiratory muscle group—were dependent on central nervous system infections originating in symptomless infections of the tonsils from which micro organisms and toxins were recovered which on injection into experimental animals reproduced identical forms of the disease." Dr Rosenow a graduate of Rush

Medical College, Chicago, is professor of bacteriology and immunology at the University of Minnesota Graduate School of Medicine

MISSOURI

Commission to Supervise New Cancer Hospital—Dr Ellis Fischel, associate professor of surgery St Louis University School of Medicine has been appointed chairman of a commission which will supervise construction and operation of a new state cancer hospital for indigents, it is reported. Names of the other three members of the commission were not announced. Creation of the hospital and a series of supplementary clinics was authorized by the last session of the legislature, which appropriated \$600,000 for construction and equipment of the institution and its operation for a year. It was stated that work cannot start until after the date on which the bill is effective, September 6. Dr Fischel is head of the cancer committee of the Missouri State Medical Association and a staff member and secretary of the medical board of the Barnard Free Skin and Cancer Hospital.

MONTANA

Hospital News—Construction of a new orthopedic hospital as a unit of the Montana Children's Home and Hospital, Helena, was to start June 21, newspapers reported. The new unit to be known as the Louis W Shodair Hospital for Crippled Children will cost about \$45,000. It is made possible through a gift of \$90,000 by Louis William Shodair, Los Angeles, who specified that half the fund be used for construction and the remainder for maintenance.

NEW JERSEY

Hobby Exhibit at State Meeting—Ninety-eight entrants sent 2072 articles to the annual art hobby and medical history exhibit of the Medical Society of New Jersey presented at the annual meeting in Atlantic City under the management of the Woman's Auxiliary. This year the exhibit included the first showing of county medical histories a project recently undertaken by the auxiliary. Nine counties had displays that included biographies, photographs, society histories, old books and medical antiques. In addition there were thirty historical exhibits entered by individuals. The art and hobby displays ranged from paintings, drawings, sculpture and photographs to Indian relics, coins and stamps. Mrs Ily R Beir Atlantic City, was chairman of the committee that arranged the exhibit.

NEW YORK

Hospitals Opened—A new eighty-two bed city hospital was dedicated in Oneida June 16 to take the place of the old Broad Street and City hospitals. Patients were moved June 29 into the new \$220,000 structure built with the aid of PWA funds. The Bath Memorial Hospital, formerly known as Bath Hospital, opened a new building with a capacity of fifty beds in May. The new hospital was built as a memorial to the late Drs Douglass H Smith and Henry J Wynkoop, Bath, with funds provided by members of their families augmented by a PWA grant of \$65,000.

New Department Heads at Albany Medical College—Dr Joseph Lewi Donhauser, associate professor of surgery, Albany Medical College, has been appointed professor of surgery and executive head of the department of surgery to succeed Dr Arthur W Elting, who retired July 1. Dr Lemuel Whittington Gorham, associate professor of medicine, will succeed Dr Thomas Ordway as professor of medicine and executive head of that department, and Dr Arthur J Wallingford, associate in gynecology, will succeed Dr John A Sampson as professor and head of the department of gynecology. Dr Donhauser and Dr Wallingford are graduates of Albany, Dr Gorham graduated from Johns Hopkins University School of Medicine Baltimore. In addition to the teaching appointments, Dr Donhauser becomes surgeon in chief at Albany Hospital and Dr Gorham consulting physician.

Commission to Study Problems of Hard of Hearing—Appointments to a temporary commission to 'examine, report on and recommend measures to improve facilities for care of deaf children and children liable to become deaf' authorized at the last session of the legislature, were recently announced by Governor Lehman. The governor's appointees are Dr Augustus J Hambrook, Troy, chairman of the committee for deaf and hard of hearing of the Medical Society of the State of New York, Dr Edmund P Fowler, director of research and clinics New York League for the Hard of Hearing, Dr Emily A Pratt, supervisor of eyes and ears, state department of education Albany, Miss Estelle E Samuelson, execu-

tive secretary of the New York League for the Hard of Hearing, and M Victor Skyberg, principal of the New York School for the Deaf. Six members of the legislature are also part of the committee and ex officio members are Dr Edward S Godfrey Jr, state health commissioner, and Frank P. Graves, LL.D. commissioner of education. The commission must report to the legislature on or before Feb 15 1938.

New York City

Hospital Temporarily Closed—Beth David Hospital closed its hospital and outpatient facilities at One Hundred and Thirtieth Street and Lexington Avenue, July 15, preparatory to moving to a new building. The new hospital at Ninetieth Street and Lexington Avenue, which will have a capacity of 200 beds, will open about September 1.

Changes in Staff of Rockefeller Institute—The board of scientific directors of the Rockefeller Institute for Medical Research announces promotions and new appointments in the scientific staff. The promotions are as follows:

Associate member to member Max Bergmann Ph D
Associate to associate member Wendell M Stanley Ph D
Assistant to associate Lyman C Craig Ph D Dr Lee E Farr
Roger M Herriott Ph D Alma E Hiller Ph D Dr Albert B Sabin
and Erich Traub VMD

The following new appointments are announced:

Assistants Otto K Behrens Ph D Washington, D C Lindsay M Black Ph D New York Dr Jacques Bourdillon Geneva Switzerland Dr Thomas M Brown Baltimore Dr Jordi Folch Pi formerly of Barcelona Spain Dr Frank H Robinson Jr Baltimore Dr Gerbard Schmidt formerly of Frankfurt Germany Dr Henry A Schroeder Philadelphia

Fellows Max A Lauffer Jr Ph D Minneapolis Dr John M Pearce, New York Richard E Reeves Ph D New Haven Conn and A Frank Ross Ph D Madison Wis

Appointments to Staff of Chronic Disease Hospital—Affiliation of Welfare Hospital, the new hospital for patients with chronic diseases, now under construction on Welfare Island with three medical schools and appointment of physicians to direct the divisions for each school have been announced by Dr Sigismund S Goldwater, city commissioner of hospitals. For Columbia University College of Physicians and Surgeons the director of medicine will be Dr Randolph West, the director of surgery, Dr William Barclay Parsons. For Cornell University Medical College the director of medicine will be Dr Irving Sherwood Wright, the director of surgery, Dr Ralph Firestone Bowers. For New York University College of Medicine Dr Norman H Jolliffe will be director of medicine and Dr William Howard Barber, director of surgery. Dr Wright has been made president of the medical board, Dr West vice president and Dr Jolliffe secretary.

NORTH CAROLINA

Personal—Dr James W Vernon, Morganton, was recently elected president of the North Carolina State Board of Medical Examiners. Dr Jabez H Williams, formerly of the staff of the State Sanatorium, Sanatorium, has been appointed health officer of Sampson County to succeed Dr Wyman P Starling, Clinton.

OKLAHOMA

Infantile Paralysis Reported—Newspapers have reported cases of infantile paralysis in some towns in Oklahoma. Bartlesville had nine active cases July 13 and two small neighboring towns had three more. Six cases were reported in Guthrie July 11. Three each were reported in Oklahoma City and in Ryan.

Society News—Among speakers at a meeting of the Southern Oklahoma Medical Association in Sulphur June 8 were Drs Bert F Keltz Oklahoma City, on 'Protamine Insulin versus Regular Insulin', Orman T Kimbrough Wichita Falls, Texas, 'Pain in the Kidney Region', and Leroy D Long Oklahoma City, 'Indications for Surgery and the Surgical Treatment of Peptic Ulcer', Richard M Burke Sulphur, 'Collapse Therapy in Pulmonary Tuberculosis', Bert E Mulvey Oklahoma City, 'Coronary Artery Disease and Joseph E Kanatser, Wichita Falls 'Obstetric Hemorrhages and Their Treatment'.

PENNSYLVANIA

Society News—The annual meeting of the Lehigh Valley Medical Association was held at Pocono Manor Inn Monroe County, July 14. Dr Charles L Brown, professor and head of the department of medicine, Temple University School of Medicine Philadelphia was the speaker on 'Digitalis Diuretics and Diet in the Management of Chronic Heart Failure'. Dr Charles E Beck, Portland president of the association.

gave his official address, on "Forty Years in Medicine"—The Fayette County Medical and Dental societies held their annual joint picnic at the Uniontown Country Club, July 21

SOUTH CAROLINA

New Members of Examining Board—The following new members have been appointed to the state board of medical examiners in recent months: Drs. Carl A. West, Camden, Daniel L. Maguire, Charleston, and Clough H. Blake, Greenwood. Dr. Josiah S. Matthews, Denmark, is president of the board, and Dr. Albert Earle Boozer, Columbia, is secretary. Other members are Drs. George R. Wilkinson, Greenville, Nathaniel B. Heyward, Columbia, and Enoch M. Dibble, Marion.

TENNESSEE

Society News—Drs. Walter T. Swink and Jacob Alperin, Memphis, addressed the Memphis and Shelby County Medical Society, Memphis, June 1, on "Treatment of Pneumonia" and "Diabetes Mellitus and Protamine Insulin" respectively. Dr. Ernest R. Zemp, Knoxville, addressed the Knox County Medical Society, Knoxville, June 29, on "Anatomical and Physiological Basis of Hypertension." At a meeting of the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society in Lawrenceburg, June 29, the speakers were Drs. Alva A. Jackson, Florence, Ala., on "Osteomyelitis", Oval N. Bryan, Nashville, "Diagnosis and Treatment of Syphilis", George C. Williamson, Columbia, "Acute Abdominal Conditions in Infancy and Childhood", and J. J. Reavis, DDS, Lawrenceburg, "Importance of Calcium and Phosphorus and Vitamins A, B, C, and D in the Child's Diet." Drs. Abraham J. Guinn, Ducktown, and John W. Bradley, Chattanooga, addressed the Hamilton County Medical Society, July 1, on tribrom-ethanol as a basal anesthetic, and venereal disease respectively. Drs. Thomas Jennings, Clinton, and Horton G. DuBard, Norris, discussed nephritis and lead poisoning respectively at a meeting of the Anderson County Medical Society, June 7.

TEXAS

Personal—Dr. Stuart P. Cromer, recently assistant medical superintendent of the Research and Educational Hospital, University of Illinois College of Medicine, Chicago, has been appointed superintendent of Baylor University Hospital to succeed Dr. Edgar M. Dunstan. Dr. Dunstan has been appointed head of the Dallas city and county hospital system. It is reported that Dr. Jarrett E. Williams, adjunct professor of pathology, University of Texas School of Medicine, Galveston, has been promoted to be associate professor to succeed Dr. John F. Pilcher, resigned. Dr. William P. Harrison, Teague, was recently elected president of the state board of health, succeeding Dr. Elbert W. Wright, Bowie.

UTAH

Society News—Dr. Frank M. McHugh, Salt Lake City, among others, addressed the Central Utah Medical Society at Salina recently on "Acute Tracheolaryngeal Bronchitis." Dr. Clyde W. Countryman, Spokane, Wash., addressed the Salt Lake County Medical Society, Salt Lake City, June 14, on "Gunshot Wounds of the Liver, with a Suggested New Method of Treatment." A special clinical meeting on muscular atrophy was held at the Latter Day Saints Hospital in the morning. At the May 10 meeting, Drs. John Mercer Anderson, George Gill Richards, and Charles Elmer Barrett presented a symposium on allergy. Dr. Samuel W. Hamilton, White Plains, N. Y., addressed the Utah County Medical Society at the Utah State Hospital, Provo, on recent advances in psychiatry, and Dr. Wilmer L. Allen, Provo, on "Deep Infections of the Neck" at recent meetings.

WEST VIRGINIA

Annual Seminar—The Golden Clinic of the Davis Memorial Hospital, Elkins, presented its annual seminar, July 14. In the morning there were case presentations at the hospital followed by a luncheon at the Randolph Hotel given by the West Virginia Heart Association. Drs. Roy Wesley Scott, Cleveland, and Louis Hamman, Baltimore, were guest speakers. At a scientific session in the afternoon at the Elkins High School, Dr. Scott spoke on Heart Diseases, Dr. Hamman on Tumors of the Abdomen, and Dr. Lawrence R. Wharton, Baltimore, on Tumors of the Kidney. The annual dinner was held at the Davis Memorial Presbyterian Church with Dr. J. Ross Hunter, Charleston, W. Va., as toastmaster. Dr. Lawrence A. Pomeroy, Cleveland, was the dinner speaker on "New Names for Old Tumors."

GENERAL

Organization to Study Convalescent Serum—A group of persons interested in convalescent serum therapy held a meeting at the Childrens Hospital, Philadelphia, June 7, and organized the American Human Serum Association. Dr. Fred M. Meader, Detroit, was elected president and Dr. Clarence M. Hyland, Los Angeles, secretary. Following are the other founding members of the association: Drs. Maurice A. F. Hardgrove, Milwaukee, Walter T. Harrison, U. S. Public Health Service, Washington, D. C., Sidney O. Levinson, Chicago, Aims C. McGuinness, Stuart Mudd, and Joseph Stokes, Jr., Philadelphia, Erling S. Platou, Minneapolis, William Thalhimer, New York, Franklin H. Top, Detroit, Paul Stephen Des Moines, Iowa, Miss Beatrice Howitt, Hooper Foundation, University of California, San Francisco, and Earl W. Flodorf, Ph.D., assistant professor of bacteriology, University of Pennsylvania School of Medicine, Philadelphia.

Fraudulent Instrument Repair Man—A physician reports the activities of a man who claims to repair surgical instruments but does not return those he takes. In Pittsburgh he claimed to renickel instruments for 25 cents and to replace broken parts of syringes at 20 cents each. Having picked up instruments and syringes, he next offered to sell a repaired instrument at a ridiculously low price. He usually said that the doctor had died while the repairs were being made and that he merely wanted the price of the repairs. Several physicians gave him cash and checks and are still waiting for their purchases, according to the report. The man said his name was W. J. Herries and gave his address as 1601 Market Street, Philadelphia, which is the Pennsylvania Railroad Station. He is between 45 and 50 years old, about 5 feet 4 inches tall, is of slight build, has thin sandy-colored hair, wears glasses and has poor teeth, it was said.

First Theobald Smith Award—Robley D. Evans, Ph.D., assistant professor of physics, Massachusetts Institute of Technology, Cambridge, received the first Theobald Smith Award in medical science at the summer meeting of the American Association for the Advancement of Science in Denver in June. Dr. Evans was honored for research that led to a method of detecting radium poisoning before its fatal stage and a treatment for extracting the radium from bones. He is 30 years old, a native of Nebraska, and received his doctorate at the California Institute of Technology in 1932. He was appointed to his present position in 1934 after spending two years as National Research Fellow at the University of California. The Theobald Smith Award was established in 1935 by Eli Lilly & Co., Indianapolis, to be awarded to an investigator under 35 years old for "demonstrated research in the field of the medical sciences taking into consideration independence of thought and originality." It consists of a bronze medal and \$1,000.

Fraudulent Sales Agent—Physicians in North Carolina and Georgia again report the activities of a man claiming to represent the Atlas Sales Company of Philadelphia and selling magazines in combination with medical books. In North Carolina he took subscriptions offering one of three medical books as a premium. He used the name W. D. Kitchens and gave the address of the firm as 1020 Walnut Street, Philadelphia. A letter to that address was returned unclaimed. In Georgia he took an order for *Life* with six medical monographs as premiums, gave his name as W. D. Kitchens and the address of the sales company as 1814 Walnut Street, Philadelphia. He gave his own address as Route 1, Box 12, Midland, Ga. A letter to the postmaster at Midland elicited the information that Kitchens was not known there and a letter to Philadelphia was returned unclaimed. Information concerning a fake agent claiming to represent the Atlas Sales Company, 1020 Walnut Street, Philadelphia, was published in THE JOURNAL, July 17, page 216. In that case the man used the name S. R. Ray. The earlier complaints came from Georgia and South Carolina.

News of Woman's Auxiliary—The *News Letter* of the Woman's Auxiliary reports the activities of the auxiliaries in various states. From Arizona it was reported that Yavapai and Yuma counties have recently organized auxiliaries, that Maricopa County members were active in the interest of medical legislation, and that Pinal County won one of three prizes of \$50 each given by Mrs. John O. McReynolds, Dallas, Texas, in a contest for subscriptions to *Hygeia*. In Idaho, the Boise auxiliary devoted much of its time to legislation, assisting in the passage of a bill providing for a state medical director and the establishment of health units and passage also of the uniform narcotic law. The Kentucky auxiliary has started a project to erect a memorial at Bowling Green to the late Dr. Joseph N. McCormack. It has under way also a memorial to Jane Todd Crawford, the patient on whom Dr. Ephraim

McDowell performed the first ovariectomy. North Carolina has started an endowment fund to support a bed in the new Western North Carolina Sanatorium near Black Mountain, it has for several years maintained a bed in State Sanatorium for physicians, their dependents and nurses. Utah members took an active part in legislative work as part of the "women's legislative council," a state organization representing women's organizations. They also had charge of two health meetings during a "woman's institute" sponsored by the *Salt Lake Tribune and Telegram* last April. This auxiliary has assembled an exhibit on quackery in the form of a circus, which has been exhibited at many fairs and conventions.

Medical Bills in Congress—Changes in Status H R 5030 has passed the House, granting increased pensions to veterans of the Spanish-American War, including contract nurses. The bill authorizes no pensions for contract surgeons. H R 6906 has passed the Senate, with amendments, proposing to regulate the use of cannabis by imposing occupational excise taxes and transfer taxes on certain dealers, including physicians who dispense or prescribe cannabis. S 2067 has passed, with amendments, the Senate and the House, to establish the National Cancer Institute and to provide for, foster and aid in coordinating research relating to cancer. *Bills Introduced* H R 7913, introduced by Representative Chapman, Kentucky, proposes to amend the Food and Drugs Act of June 30, 1906, as amended to bring within the purview of the act therapeutic devices and cosmetics and to redefine the terms "food" and "drug." H R 7959, introduced (by request) by Representative Sparkman, Alabama, proposes to provide for federal service medals of honor to government employees who while in the employment of the government have made outstanding contributions to the advancement of scientific knowledge or the application of its truths in a practical way for the welfare of the human race or who have rendered conspicuous service to humanity at the voluntary risk of life or health over and above the ordinary risks of duty. H R 7971, introduced by Representative O'Connell, Montana, proposes to regulate interstate commerce in goods produced under conditions exposing employees to the hazards of silicosis and related dust diseases. The Secretary of Labor is authorized to conduct investigations to determine the existence, nature and extent of such hazards and to require the installation, maintenance and effective operation of devices and safeguards to eliminate the hazards.

CANADA

Canadian Medical Association—The sixty-eighth annual session of the Canadian Medical Association was held in Ottawa June 21-25. The guest speakers included

Mr. Reginald Watson Jones University of Liverpool England
Mr. Harold Beckwith Whitehouse Birmingham England
Dr. Albert M. Snell Rochester Minn. Medical Aspects of Jaundice
Dr. Benjamin P. Watson New York Postpartum Sepsis
Dr. John S. Lundy Rochester Minn. The Present Unusual Opportunities for Medical Men in Anesthesia
Dr. Ralph M. Waters Madison Wis. Carbon Dioxide
Dr. Maurice Brodie New York Recent Immunologic and Pathologic Studies in Poliomyelitis and Their Significance
Dr. Perrin H. Long Baltimore Clinical Use of Para Amino Benzene Sulfonamide or Its Derivatives in the Treatment of Beta Hemolytic Streptococcal Infection
Dr. Franklin F. Snyder Baltimore The Normal Occurrence of Fetal Respiration and Its Relation to the Abnormalities of the New Born
Dr. Philip D. Woodbridge Boston Important Minor Points in Local Anesthesia

Government Services

Dr. Francis Ill with Relapsing Fever

Dr. Edward Francis U. S. Public Health Service is at the Marine Hospital, Baltimore slowly recovering from relapsing fever according to the *New York Times*. It was stated that Dr. Francis allowed himself to be bitten by a tick in a laboratory experiment. For five years he kept thirty ticks infected with relapsing fever in a pill box without food or water, according to the newspaper report. Then a monkey bitten by one of these in an experiment developed the disease proving that five years' starvation not only did not kill the ticks but did not kill the organisms they harbored. To determine whether the organism is transmitted to later generations of ticks and whether it was still capable of causing the disease, Dr. Francis allowed a second generation tick to bite him and as a result he developed the fever. Dr. Francis graduated at the University of Cincinnati College of Medicine in 1897 and joined the public health service in 1900. He was appointed medical director in 1930. In 1928 the American Medical Association awarded him a gold medal for contributions to knowledge of tularemia.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 3, 1937

The Editor of the *Lancet*

Sir Squire Sprigge, editor of the *Lancet* died within a few days of completing his seventy-seventh year. He was in active work almost to the end. Educated at Cambridge and St. George's Hospital, he graduated in medicine in 1887 but from the first showed a literary bent and no desire to take up practice, though he held various resident and traveling appointments. He wrote short stories in magazines and did some medical reviewing. He became secretary to Sir Russell Reynolds, whom he assisted in his literary work. He also became secretary to the Society of Authors, of which he later was chairman. The key to his important career is that he was the literary man turned medical journalist, a description which does not apply to any other member of that profession. At the end of 1892 he joined the staff of the *Lancet* on probation, by request of the editors, and soon was appointed assistant editor. The journal was then under the control of the son and grandson of the founder, Thomas Wakley. Sprigge had not been there long when he was commissioned to write the history of the founder and the early work of the *Lancet*. This appeared as a serial and afterward in book form under the title "The Life and Times of Thomas Wakley." With the appearance of the *Lancet* in 1823, English medical journalism assumed a new form. The novelty consisted in not only supplying medical information but in standing up for the rights of the doctor. Wakley was a great medical reformer who exposed the nepotism and inefficiency then rife in the medical schools. He increased the exasperation of their staffs by publishing their lectures, a thing never done before. They objected for fear that they might lose some of the fees paid by students. An acrimonious controversy, sometimes, as was customary in that age, even scurrilous, was waged. The tone of the *Lancet* was then very different from the staid respectability of later years. The whole story is vividly and admirably told in Sprigge's book, which is an important contribution to the history of medicine in England in the first half of the nineteenth century. With the death of Wakley's grandson in 1909 the *Lancet* passed out of the family and Sprigge became editor. He filled the position with distinction and was an important figure in both the medical and literary worlds. He was master of all the personal, social and political aspects of medicine. He was an authority on medical education, on which he published a book in 1910. In 1920 he was vice president of the section of medical education at the annual meeting of the British Medical Association. In 1921 he and the editor of the *British Medical Journal*, Dr. Dawson Williams, were knighted for their services in medical recruiting and in other ways during the great war. In medical politics he was a statesman on whom the profession could always rely for sane leadership in the difficult crises of recent years.

Rehabilitation of Injured Persons

Fracture clinics have been established in this country because they gave results much better than those of unorganized treatment. Last April the government appointed a committee, containing surgeons experienced in the treatment of fractures, to inquire into the arrangements at present in operation with a view to the restoration of persons injured by accidents, and to report as to what improvements or developments are desirable. The committee was directed to have regard to the Report on Fractures issued by the British Medical Association (*THE JOURNAL*, March 16, 1935, p. 934), which recommended the

concentration of cases in one department under single control, continuity of treatment and supervision until rehabilitation. The committee made a survey of the hospital arrangements of the country for the treatment of fractures and presented its report, which has just been published. Information was received from 724 voluntary and 101 municipal hospitals covering 201,732 new fracture cases treated in 1935. In 650 hospitals all cases were treated under the general surgical routine, fifty-nine hospitals had fracture departments organized on lines which appeared to conform to the principles stated, 116 other hospitals had partially organized fracture clinics. The committee prepared a scheme for the organization of fracture clinics and submitted a draft of it to a number of representative hospitals and authorities for their observation. In the meantime the question of providing fracture clinics was receiving consideration in many different quarters as a result of growing dissatisfaction with the results obtained under the old methods. Hospital authorities, local government authorities and employers' and workers' organizations took up the question. Some clinics were established and others were planned, and the committee was asked for guidance. It therefore decided to issue an interim report on the organization of fracture clinics, without waiting to complete its inquiry into other questions, such as the manner in which expenditure should be met, methods of rehabilitation after clinical treatment and provision for other kinds of injury.

ORGANIZATION OF A FRACTURE CLINIC

The scheme is based on the assumption that the clinics will be established as an integral part of existing hospitals, though independent clinics in a few centers, at which methods of treatment would be made the subject of special study, are not ruled out. The object is to bring all fracture cases under unified control and to ensure that the treatment shall continue under the same supervision until rehabilitation is complete. This can best be ensured by concentrating all cases in a separate department of the hospital. Where it is not possible under existing conditions to set aside separate wards for the purpose, certain beds in the general wards should be definitely assigned to the fracture department, pending the provision of separate accommodation. The department should be placed under the charge of one of the visiting surgeons, and one or more whole time assistants will be needed. An X-ray technician must always be available at any time of the day or night, so that there may be no delay in examination, by which alone treatment can be accurately controlled. The committee recommends one departure from ordinary practice in hospitals. It is not the custom for the visiting staff to receive any remuneration. But the surgeon in charge of the fracture clinic will undertake much more onerous duties than those usually falling to a visiting surgeon and probably will have to give up other remunerative work. He should therefore receive some honorarium. Unless this is done it may be difficult to secure the man best qualified for the work.

The arrangements for fracture clinics vary with their size. The maximum size compatible with unified control is one capable of dealing with from 3,000 to 3,500 cases a year, of which about one third would need inpatient treatment, involving the provision of forty beds. The needs of rural areas not served by a local hospital capable of maintaining a fracture clinic should be met by linking them up with one at some convenient center to which cases could be transferred. Outpatient treatment could be carried out locally, subject to supervision from the center. Thus the plan of the committee is to provide a network of fracture clinics covering the whole country. Its solution requires the cooperation of all the interests involved—the local government authorities, the larger voluntary hospitals in the more important centers, the smaller institutions in rural areas, the medical profession, the ambulance services, and employers' and workers' organizations.

The Changed Outlook in Mental Disease

Sir Kingsley Wood, minister of health, opened a new mental hospital at Runwell, Essex, which has been laid out on garden city lines, and in its twenty-five units, each planned for a specific purpose, a community of 1,010 patients and a staff of about 400 are housed. The buildings are separated by wide lawns and by flower and vegetable beds. Wide verandas with solariums form a feature of the patients' units, and airy rooms with French windows enable them to feel that they are in a sanatorium. Addressing the large audience present in the recreation hall, Sir Kingsley Wood said that the national outlook toward mental disease had completely changed in recent years. The old term "asylum" had disappeared and so had "lunatic," which was not only misleading but mischievous, because it ignored the fact that there were many forms of mental disorders with different causes. Great progress had been made in humanizing mental hospitals, and the whole atmosphere and outlook were quite different from the days when mental disease was treated more like a criminal offense than anything else. Increasing numbers were voluntarily seeking treatment in hospitals in the early stages of the disease, last year 2,500 patients of this kind were admitted to public mental hospitals. Occupational therapy and recreation were playing an increasingly important part in the treatment of mental disorders, and there was greater organization of outdoor games and dancing. He did not think that there was proof that the incidence of mental disorders in this country was rising. Probably something like one third of all sickness, apparently physical, was, in fact, nervous in origin.

The Use of Radioactive Thermal Waters

Before the section of physical medicine of the Royal Society of Medicine, Dr C. W. Buckley, balneologist, opened an important discussion on the indications for the use of radioactive thermal waters. He said that the thermal effects on the system from the use of water at various temperatures, and the mechanical action of douches, was much the same whatever water is used. But for the more severe types of chronic rheumatic disease the chemical action of the water used on and through the skin makes a material difference to the permanence of the relief, not to say cure. Thermal and mechanical effects are not those of chief importance. A criterion of the chemical action involved in the external use of mineral waters of the type of Buxton is the occurrence of "bath reactions." Simple immersion in the Buxton natural pool for fifteen or twenty minutes produces very different results from those after immersion in an ordinary swimming pool. The usual effect is a disproportionate lassitude accompanied by muscular pains and aches. If there is a tendency to gout, this effect is more marked and may culminate in an acute attack. As the patient is likely to have been taking a daily bath at home, the chemical activity of the water must be responsible for this effect, which is due to its action on metabolism.

Recent researches in France by Mougeot and others have shown that with gaseous waters osmosis takes place through the skin but that the gases are absorbed in much greater quantity through the lungs. They are continuously given off from the surface of the water in which the patient is immersed, and as they diffuse very slowly the layer of air which he breathes is richly charged with them and with radon, if present.

The benefit of radioactive waters and baths in rheumatic diseases is generally admitted, but doubt exists as to their use in the more acute stages of rheumatoid arthritis. Dr Buckley held that warm immersion baths, large and deep enough to permit of movements being freely carried out were valuable at any stage of this disease. Fibrositis, including sciatica and brachial neuritis, is an important indication, especially in cases due to toxic or infective causes while those due to strain or other forms of trauma are also likely to benefit. Osteo-arthritis is another indication, although the possibilities of improvement depend on the state and the extent to which fibrositis is asso-

ciated But gout is the disease above all others which benefits by radioactive waters at any stage, both for prophylaxis and for treatment In all these cases there is a certain specific action, the "bath reaction" mentioned This is probably of the nature of a mild protein shock and needs to be carefully controlled

Certain forms of hepatic disorder and catarrh of the colon due to residence in a hot climate and often the sequel of dysentery appear to do well High blood pressure of the type so often met with in women at the menopause is benefited by these baths and the eliminative effect of a diuretic water

Iodized Oil as a Test of Pancreatic Function

The external secretion of the pancreas, as distinguished from its internal secretion, has such an important part in digestion that it is often necessary to determine its activity It is difficult to carry out such a study clinically, because the symptoms of deficiency are indefinite F Tremolieres read a paper at the May 25 meeting of the Academie de medecine on a method which could be used to enable the clinician to determine if not the composition of the entire pancreatic secretion at least that of one of its constituents His method consists in having the patient take, before breakfast, five capsules of iodized oil corresponding to 1 Gm of iodine As shown by the experiments of Rene Fabre, in collaboration with Sicard and Forestier and with Binet, the iodine is rapidly absorbed and is excreted by the kidneys, so that it is justifiable to assume that the elimination is proportional to the absorption It is sufficient, therefore, to collect the urine for twenty-four hours and to estimate its iodine content by the Cheramy method In normal persons the amount of iodine eliminated is about 50 per cent of that which has been ingested This method permits an estimation of the secretion of lipase The effect of the pancreatic lipase is, on the contrary, so much greater than that of the intestinal lipase that its estimation is not obscured The method has been employed in more than 200 cases with the following results 1 When examination of the feces, following a test meal, reveals a pancreatic insufficiency, the proportion of iodine eliminated is usually from 20 to 30 per cent, always more than 13 per cent and distinctly less than the normal 50 per cent 2 In cases of associated hepatic and pancreatic insufficiency the lowest percentages are found, lower than 25 per cent and going down as low as from 3 to 5 per cent 3 When the feces examination does not indicate any alteration of biliary and pancreatic function, the assimilation of iodine is close to the normal 50 per cent

The method is so simple that it merits, according to Tremolieres, further trial as a routine test of pancreatic function

Influence of Therapy on Dementia Paralytica

A statistical study of 3,000 patients admitted between 1920 and 1933 to a psychiatric hospital here appears in the May 29 issue of the *Presse medicale* The authors, Drs P A and C Chatagnon, have noted a change in the clinical picture as the result of changed social conditions and the newer methods of treatment They found that the number of men suffering from dementia paralytica increased markedly (about double) between 1926 and 1932, reaching a maximum from 1926 to 1927 and especially in 1928 The latter increase probably corresponds to syphilis acquired during the World War years There was an equally marked decrease in the number of admissions for dementia paralytica in 1933 There is less fluctuation in the case of women admitted between 1920 and 1933 The average number of patients admitted during these thirteen years as compared to that for other diseases was 55 per cent for women and 13.5 per cent for men The effect of modern therapy is more marked in the case of men suffering from dementia

paralytica than in that of women This explains the decreased number of male admissions as compared to that of females A striking decrease in the mortality for both sexes is to be noted as the year 1933 is approached, probably as the result of more energetic treatment With few exceptions, all the patients included in the statistics were treated with pentavalent arsenical preparations, mercury and bismuth compounds and also malaria

Variations of Mortality and Natality in France

Dr Marcel Moine, statistician of the French national committee for the control of tuberculosis, presented at the May 11 meeting of the Academie de medecine a study of the variation in the number of deaths and births in France from 1810 to the present time The study shows that the decreased number of births has been partially compensated by a noteworthy decrease in the number of deaths, especially in the past seventy years If the mortality had remained stationary, taking in consideration the diminution of the natality, the population of France in 1931 would have been only 28,400,000 instead of 41,800,000 If, on the other hand, the natality had remained the same as it was between 1810 and 1830, the population would have been 89,100,000 in 1931, more than double the actual figure for that year Compared to other countries in which the decrease in the number of deaths annually has been even more marked than in France, it is possible still to expect a decrease of 180,000 deaths a year This decrease alone would not, however, be able to equalize the number of deaths and births, if the number of the latter continue to decrease as is at present the case

New Regulations on Prevention of Venereal Diseases

In a letter sent by the minister of public health, Dec 10, 1936, to all antivenereal dispensaries, the latter were instructed to organize their social service departments Special stress was laid on the necessity of investigating the source of contamination in every new case of syphilis There should be close cooperation between the antivenereal and military services The precise nature of this cooperation is outlined in instructions sent out on April 16 to be applied in the central ministries (departments of the central government) in Paris and by the individual departmental representatives of the central government at Paris In the former (central administrations) there shall be cooperation between the commission on prevention of venereal diseases and the committee for the study of venereal disease in the army These two committees have, as members, representatives of the war and public health departments There shall be constant exchange between them of information regarding the development and prevention of venereal disease

Federation Recommends Higher Fees

As explained in previous letters, there is an organization in each of the eighty-six departments termed the medical syndicate of the respective department, which looks after the interests of the profession At the May 9 meeting of the executive committee of the Central Federation, the following resolution was unanimously passed "In view of the 30 per cent devaluation of the franc in September 1936 and the increased cost of living, the officers of the federation are authorized to take the necessary steps to increase the fees for services to veterans, accident cases, house and office visits 30 per cent" This step has been rendered necessary because of the constantly decreasing income of members of the profession, especially in larger centers of population

Twenty-Fourth Hygiene Congress

The twenty-fourth annual meeting of the French Hygiene Congress will be held October 18-19 in the Pasteur Institute The president this year is Dr Lesne, a pediatrician The subjects selected for special discussion are (1) overworked school children from the medical, social and administrative points of

view, (2) prophylaxis of tuberculosis in schools, (3) backward children in city schools and (4) healthful milk. Those who wish to take part in the program may write to Dr. R. Dujarric de la Riviere, 28 rue du Docteur-Roux, Paris (15).

The Prophylaxis of Diphtheria

Professor Prigge of the Institute of Experimental Therapy at Frankfurt-on-the-Main has made a study of protective inoculation against diphtheria. Active immunization, although extensively used abroad, gained little headway in Germany as part of the antidiphtheria armamentarium until a few years ago, the reason being that the immunizing power or protective value of the vaccine could not be estimated with any degree of accuracy. Whereas it was possible, to be sure, to determine with exactitude the harmlessness of a vaccine, it was impossible accurately to distinguish the effective from the ineffective. Animal experimentation, too, offered next to nothing that would help surmount the difficulties arising from the lack of a standard whereby the inoculation serum could be evaluated. Prigge established that the underlying cause for this failure was the great individual variation in the susceptibility to immunization of animals obtained through the usual commercial channels. Whereas the capability of reactive animals to numerous other biologically effective substances is markedly uniform, the conditions with respect to vaccines is altogether otherwise. The quantities of serum necessary to protect the animals which are most difficult to immunize are some 30,000 times greater than the doses sufficient to immunize the animals exhibiting the greatest powers of reaction. Prigge found that this variability could be reduced experimentally in guinea-pigs. After a progressive inbreeding of brothers and sisters over a period of years, the range of immunizing dosage was in favorable instances reduced till the maximal dose was only twenty-five times the minimal. Even this degree of variability, however, rendered the application of the customary biologic method of evaluation out of the question. Prigge also observed temporary variations in the reactions of whole groups of animals. The latter variations endured for several years, and investigation along this line promises to yield data of epidemiologic import. Only after meticulous analysis of all these concomitant circumstances was Prigge able to evolve a working basis for evolution of the immunizing power of diphtheria serum. The method by which the objective was obtained was an application of Fechner's law to the animal material. Even the difficulties arising from the constant variations in reactive capability in the animal material were completely surmounted and it became possible to check each measurement against an absolutely stable standard. Since 1934 the capability of immunization of all antidiphtheric protective vaccine on the German market has been subjected by law to the foregoing test. Furthermore, the establishment of a precise method of evaluation has made possible the rapid development of a more highly potent vaccine. Prigge was also able to demonstrate conclusively that the treatment of serum with various substances (aluminum, potassium alum and later aluminum hydroxide) increased its effectiveness, in some instances as much as a hundredfold. This method of treating the serum although made known in 1925 had been the subject of controversy and in Germany had been rejected. It may be expected that on the basis of the new technique a single inoculation will come to supersede the three injections. In various cities more than 100,000 children have already been immunized with the aluminum vaccine.

Reorganization of German Health Resorts

Reorganization of German health resorts has been contemplated (*THE JOURNAL*, Dec. 23, 1933, p. 2062). Pending definitive regulation by a national statute of health resorts,

the conduct of such places will be governed by the "Guiding Principles for the Regulation of German Health Resorts," which have been formulated by the German Society for Balneotherapy and Climatotherapy in collaboration with government officials. All resorts must pass inspection on the basis of the new regulations before Jan. 1, 1938. Three types are differentiated: (1) climatotherapeutic resorts, (2) fresh air resorts and (3) summer resorts, winter resorts, convalescent resorts, tourist resorts and winter sport resorts. Use of the bare term "health resort" without some qualification such as "mountain health resort" or "winter health resort" is to be abandoned.

A local sanatorium in collaboration with the national weather bureau must be equipped to record precise scientific data on the climate and its effects and to submit detailed reports. The medical activities at these resorts must be in charge of specially trained physicians. All health resorts must comply with certain standard requirements of sanitation, drinking water, sewage, hotel accommodations, attending personnel, exclusion of disturbing noises and so on.

Special advisers and inspectors have been appointed to supervise standardization of the health resorts. Cooperative endeavor seems to assure the success of the much needed reorganization.

Psychic Variations in Uniovular Twins

One is frequently surprised to observe manifest psychic variations in a pair of uniovular twins whose bodily and physiologic character are analogous. Geyer has reported his investigation of this problem to the Berlin Medical Society. In 289 pairs of twins observed by him, the psyche was more often dissimilar than similar, 64 per cent of uniovular pairs were mentally different. Bouterwek attributes such variations to difference in symmetry, according to his opinion the halves of the human body are congenitally dissimilar and thus it happens that the division of the germinative anlage of twins does not take place in exactly equal measure. Geyer rejects Bouterwek's theory of variations. To illustrate his view, he provides a detailed character analysis of two pairs of uniovular twins. The first pair were cyclothymic pyknic types, one of whom developed in the direction of the hypomanic and the other in the direction of the melancholic component of Kretschmer's diathetic proportion. The other twins were leptosomatic schizophrenic brothers. One of them represented the anesthetic-irritable pole, the other the hyperesthetic-autistic pole of Kretschmer's psychesthetic proportion.

The National Statute of Pharmacists

Similar to the "national statute of physicians" (*THE JOURNAL*, Feb. 15, 1936, p. 551) is a recently enacted "national statute of pharmacists," which embodies a comprehensive legal regulation of pharmaceutical affairs. The new law provides for the granting, the withholding and the revocation of the pharmacist's license. It also establishes a national chamber of pharmacists. This body is empowered to adjudicate all questions of professional duty and to uphold professional ethics. The national chamber is subdivided into regional chambers. The presiding officer of the national chamber bears the title "National Fuehrer of Pharmacists." He acts as an adviser to the entire profession. All German pharmacists belong to the national chamber with the sole exception of pharmacists on active service with the defense forces.

Professor von Krehl Dead

Prof. Dr. Rudolf von Krehl, Heidelberg clinician, died after a long illness May 26, in Heidelberg, aged 75. He was numbered among the "pupils of Curschmann," who formed in Germany such a large proportion of university professors and research workers in internal medicine. Later Krehl came to Marburg, by way of Jena, as ordinarius and after Marburg he occupied the same position successively at Greifswald and Strasbourg and from 1906 at Heidelberg, where he headed the clinic of internal medicine until 1930. After he had relinquished

his professorial duties at the age of 70, he was appointed director of the new Research Institute of Internal Medicine established at Heidelberg by the Kaiser Wilhelm Foundation. Krehl's scientific training lay along the lines of that experimental physiology of which Curschmann and Carl Ludwig were the principal exponents at Leipzig. A problem which early enlisted Krehl's attention was that of the circulation in heart disease. The work that made him famous is his "Pathologic Physiology," which has exerted its influence on each new generation of physicians for more than forty years. This work was the first to be written from a truly clinical point of view. It might be said that Krehl's supreme contribution was the removal of the fulcrum of research out of the laboratory and into the clinic. He understood how best to evaluate the myriad activities of a scientific clinic. Recently he opposed, with all the wisdom born of his vast experience, the wild theories of the nature cure extremists. In his personal contacts Krehl exhibited a sympathetic, lovable character and to the end he maintained his interest in the opinions and aspirations of the younger generation. He leaves a multitude of friends and adherents.

ITALY

(From Our Regular Correspondent)

June 30, 1937

Congress of Psychiatric

The twenty-first national congress of the Società italiana di psichiatria was recently held at Naples under the chairmanship of Professor Donaggio. The first official topic was the clinical evolution and pathologic anatomy of circumscribed atrophy of the brain (Pick's disease). Drs. Chailiol and Bonfiglio of Rome were the speakers. Pick's disease gives symptoms of associated focal and general dementia. The anatomicopathologic study of the disease shows circumscribed zones of cellular atrophy of the brain. The disease has been considered a variety of senile dementia with atrophy secondary to vascular spasm, an early phase of hereditary degeneration, or a predisposition of the brain tissue to degenerate. The causation of the disease is not clear and its place in a nosologic classification is not as yet definite. Pick's theory, by which the disease is considered a variety of localization of senile dementia, is not generally accepted. The disease cannot be placed in a group with Huntington's disease or with the forms of cerebellar and olivary pontile cerebellar atrophy because of the fact that the results of studies on the subject are insufficient to justify the classification.

Professor Bonfiglio differentiated a special form of Pick's disease with atrophy circumscribed to the nuclei of the base, especially the caudate nucleus. The symptoms are iterative, of a palimimic and palilalic type, without asymbolic, apraxic, aphasic, hypokinetic and extrapyramidal motor symptoms. The mental symptoms of circumscribed atrophy of the brain are those of general dementia without any differential characteristics from those caused by other brain diseases. The apparent conflicting opinions of the two speakers in differentiating the neurologic from the mental symptoms show the general difficulties in the differentiation. The diagnosis of Pick's cerebral atrophy is difficult.

The second topic was psychosis and diseases of the metabolism. Professor Penta of Naples was the speaker. Drs. De Marco and Zara were collaborators. The discussion involved the relation between mental disorders and the diseases of the liver, the kidney and the pancreas. Determinations of the metabolisms of the fats, the water and the mineral salts of the body fluids in mental diseases have been done. Acetonuria and acetonemia, with the consequent acetonemic vomiting, are due to alterations of the fat metabolism. The amount of cholesterol in the blood is increased in all cases of manic-depressive psychosis. The alterations of the fat metabolism in mental

diseases, however, are not causal factors of the disease. Adrenal cortex extract is of no value in the treatment of mental diseases.

According to Dr. De Marco, hyperazotemia, in certain forms of acute mental diseases, is secondary to alterations of the central nervous system as the functions of the nervous centers at the pons, in regulating azotemia, have been already verified.

Dr. Zara said that the field of the relation between psychosis, the metabolism of carbohydrates and the pancreatic diseases is circumscribed. He pointed out the constant presence of abnormalities of the sugar metabolism in these conditions and the special emotive mimetic, humoral and sympathetic symptoms of psychosis or anxiety.

Anatomic Abnormalities

Professor Bellelli, at a recent meeting of the Accademia delle Scienze Mediche e Chirurgiche of Naples, reported three cases of triphalangia. Two brothers without other abnormality had three phalanges on each of their two thumbs. In another case the condition was unilateral in a hand lacking the fourth finger. The speaker regards the existence of three-phalangeal thumbs as a phenomena of antique atavistic regression by which the hand with five equally developed fingers is similar to that with five rays of the primary hands. The middle phalanx is the one that is destined to disappear. The statement seems to be supported by the fact that this phalanx is less developed than the first and third ones. The middle phalanx fixes either on the first or on the third one and not necessarily on the third one, as Pfizner stated. The third phalanx does not derive from absorption of the middle one but it originates in a process of transformation and adaptation. The first metacarpal bone of three-phalangeal thumbs is anatomically and roentgenologically equal to the metacarpal bones of normal thumbs, except by its relation to the abnormal phalanx. The causal factor of different ossification and direction of the nutrient canal of the metacarpal bone of three-phalangeal thumbs is unknown.

Dr. Lanzillo, at the same meeting, reported a case of a supernumerary muscle of the leg, which was present within the extensor muscle of the great toe and the common extensor muscle of the other toes. It originated at a point in the lower third of the lateral aspect of the tibia, continued in a 10 cm long tendon, which inserted on the anterior aspect of the articular capsule at the tibia and the astragalus, and formed a strong ligament, 5 cm in length and 1 cm in width from the internal malleolus to the lateral portion of the neck of the astragalus. He regards the muscle as a variety of the anterior tibial muscle from a reduplication of the latter. The transverse ligament of the astragalotibial articular capsule in normal conditions does not exist or is of rudimentary size.

Cholesterol in Gallbladder

Professor Baiocchi of Naples, in a paper recently read before the Società di Chirurgia, reported his studies on the quantitative variations of cholesterol in the walls of the gallbladder in normal and in pathologic conditions. His determinations were made on gallbladders of dogs, cadavers and patients with different forms of cholecystitis. Cholesterol in the walls of the gallbladder in experimental cholecystitis follows the same behavior as that in the blood and organs of patients with acute cholecystitis. It increases during the peak of the infection, becomes normal when the infection improves, and diminishes near death. In noncalculous and chronic calculous cholecystitis and pericholecystitis there is an increase of between 15 and 37 Gm of cholesterol per hundred grams of the wall. The increase of cholesterol is related to the intensity of inflammation of the structure. The amount of cholesterol in the walls of normal gallbladders is that found in any normal tissues and organs and does not show cholesterol secreting or storing functions of the walls. The behavior of cholesterol in the walls of normal and pathologic gallbladders shows that the walls have little to do with the pathogenesis of biliary lithiasis.

BELGIUM

(From Our Regular Correspondent)

May 29, 1937

The Acute Pancreatitides

Messrs Applemans and Van Goidsenhoven reported before the Belgian Society of Gastro-Enterology their observations on seventeen cases of acute pancreatitis, sixteen of which were of lithiasic-vesicular origin. Operative treatment was given in twelve of the cases. Of the five cases in which no operation was performed, one ended fatally. Of the twelve interventions, three were considered emergency operations and two of the latter ended fatally as the result of pancreatic hemorrhage. The nine operations performed after more adequate preparation were followed by recovery (edematous lesions). The pathogenesis is to be explained on the basis of alterations in the bile ducts, so that in cases of vesicular lithiasis operative treatment to prevent pancreatitis may be indicated, at least if there is a history of pain referable to the left side, diastasia or, most important of all, glycemia. Every means should be utilized in order to arrive at an accurate diagnosis before intervention is attempted. Should intervention be regularly performed? Some surgeons favor such a procedure because of the possibility of false diagnosis. The authors feel that laparotomy is too serious an intervention to be performed unless the operator has a good understanding of the disorder in question. Not all cases of acute pancreatitis will require operative treatment, but it is of paramount importance that no intervention should be decided on hastily. If the disease assumes a hemorrhagic form, operative treatment without adequate preparation will be harmful, medical treatment should therefore be carried on for several hours at least. If the pancreatitis is of the edematous type with steatonecrosis, it is also necessary to permit the shock to subside, meanwhile supplying medical treatment, namely, hypertonic serum, dextrosed serum and insulin. The intervention designed so far as is possible to abolish the cause, consists of a cholecystectomy with drainage of the pancreatic region in some cases. In the suppurative cases, incision of the abscess is the obvious indication. Postoperative relapses can mean only that the medical treatment has been inadequate.

Physical Education in the Schools

Messrs Rene Ledent of Liege and Charles Dam of Brussels discussed the organization of physical education in the schools before the Societe belge d'education physique et de sports. The authors discussed in particular the special problems presented by abnormal children. These exceptional children are far more numerous than a person unfamiliar with the facts would suspect and, moreover, they require more medical care than all others. The previous report, in 1934, of an investigating committee provided estimates of the number of children in whose physical upbringing the school physician ought to evince a special interest. According to that report from 20 to 30 per cent of school children in all Europe were affected with scoliosis and bad posture. In Belgium, 5 per cent of children in the elementary schools receive special care on account of orthopedic disorders. This low figure would lead one to surmise that too few children were receiving needed care. Orthopedists are aware of the slight attention commonly accorded various types of neurolocomotor disturbances and to the frequent neglect from which the crippled child suffers. Physically infirm form 10 per cent of the total group, mentally abnormal 5 per cent. With regard to respiratory disturbances, the authors point out that in some localities the proportion of children suffering from them is only 6 per cent, whereas the figure elsewhere is 40 per cent. The higher percentage would seem to correspond more nearly with actuality. A revision of all statistics, to be based on standardized tests, is recommended.

The authors proposed the following resolution, which was unanimously adopted. The Societe medicale belge d'Education

physique et de Sports believes that physical education, although normally a part of the school curriculum, does not always conform to certain established and recognized standards. Accordingly, the Societe resolves: 1 To see to it that the budgets of all elementary schools contain ample provision for well organized gymnastics, games and sports among the pupils of all grades. 2 That the medical supervision of physical education be administered by regular school medical inspectors. 3 That these medical officers be selected from among graduates in physical education.

Amebic Dysentery

Dr Moulaert reports the results of an investigation of the incidence of chronic amebic colitis in Belgium. Studies were made of amebic cysts in the stools of ninety-nine patients; seventy-four of these persons were of Belgian birth and had never traveled in tropical or subtropical regions, eighteen were former colonials and seven were recent arrivals in Belgium or were in transit through the country. Examination of the specimens was carried out according to the technique of Carles and Barthelemy and the cysts were observed in the excreta of 72.62 per cent of the first group of persons, in 72.22 per cent of the second group and in 57.14 per cent of the third group. The author concludes that chronic amebiasis is more prevalent in Belgium than is commonly believed. He attributes this high incidence to the importation and dissemination of the disease throughout the kingdom by the demobilized troops in 1918 as well as to the presence of colonials on holiday and former colonials resident in Belgium.

The author points out the necessity of preventing contagion. This can best be accomplished by the speediest possible detection of persons who are carriers of the cysts. Such persons always present some colonic lesions or complaints (Craig).

Marriages

HARRISON L. McLAUGHLIN, New York, to Miss Aimee Virginia Bisgood of Sag Harbor, L. I., N. Y., April 3.

LAWRENCE F. ISENHART, Mount Carroll, Ill., to Miss Marjorie Knowlton of Chicago, in Oregon, April 1.

HERBERT H. SMITH, Brookline, Mass., to Miss Marion Elizabeth Hobbs of Bronxville, N. Y., April 16.

GEORGE WILBUR WRIGHT, Clifton Springs, N. Y., to Miss Elizabeth Kompa in Brooklyn, April 30.

ROBERT LEE PATTERSON JR., Athens, Ga., to Miss Margaret Douglas Sloane of New York, May 1.

CURTIS HORTON BAYLOR, Rochester, N. Y., to Miss Catherine Burns of Lebanon, Va., April 10.

EDWARD B. WINHELD, Philadelphia, to Miss Ethel M. Schenck of New York, March 19.

NOWELL DARDEN NELMS to Miss Virginia Bell Newsom, both of Newport News, Va., April 13.

IRA EUGENE HARRIS JR., Miami, Ariz., to Miss Marjorie Ann Horan of Inspiration, March 29.

HERBERT A. CARLSON, Minneapolis, to Miss Eleanor Mann of Dickinson, N. D., recently.

ALVIE CARL WALKER to Miss Suzanne Crawford, both of Waynesburg, Pa., March 12.

FRANCIS GILBERT ZEIER to Miss Angeline Catherine Jochum, both of Chicago, recently.

CHARLES E. BORAH to Miss Josephine McKellips, both of Phoenix, Ariz., March 5.

LEVI A. COLEMAN, Salisbury, N. C., to Miss Janet Monroe of Charlotte, April 3.

GEORGE ERBEN THOMAS to Miss Marie F. Cannon, both of Philadelphia, May 19.

JOHN W. GRIFFIS to Miss Kathryn Sexton, both of Denton, N. C., March 6.

ALBERT G. MARTIN to Miss Ruth Baker, both of Aurora, Ill., May 1.

PHILEMON C. ROY, St. Paul, to Miss Alice Bartles, May 26.

Deaths

John Woolman Churchman, New York, Johns Hopkins University School of Medicine, Baltimore, 1902, formerly professor of experimental therapeutics at Cornell University Medical College, instructor in surgery at his alma mater, 1909-1911, assistant professor of surgery at Yale University School of Medicine, New Haven, 1912-1914, and later professor, at one time on the staff of the New Haven Hospital, chief physician of the French military hospital at Passy, France, in 1916, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, in 1921 received the Alvarenga Prize of the College of Physicians of Philadelphia for his work "Selective Bacteriostatic Action of Gentian Violet", in 1915 was awarded an honorary degree by Yale University, aged 60, died, July 13, at Amityville, L. I., of cerebral hemorrhage

Charles Dunbar Roy, Atlanta, Ga., University of Virginia Department of Medicine, Charlottesville, 1889, chairman of the Section on Laryngology, Otology and Rhinology of the American Medical Association, 1910-1911, and member of the House of Delegates, 1910, 1911 and 1914, emeritus professor of otology, rhinology and laryngology, Emory University School of Medicine, formerly clinical professor of eye, ear, nose and throat diseases and professor of otolaryngology at the Atlanta College of Physicians and Surgeons, member and past president of the American Laryngological Association and the American Laryngological, Rhinological and Otological Society, member of the Medical Association of Georgia and of the American Ophthalmological Society, served during the World War, aged 70, died, July 5, of cerebral thrombosis

William Hall Goodwin Ⓢ Charlottesville, Va., University of Virginia Department of Medicine, Charlottesville, 1908, professor of clinical surgery and gynecology at his alma mater, served during the World War, member of the Southern Surgical Association, fellow of the American College of Surgeons, visiting surgeon to the University of Virginia Hospital, aged 55, died suddenly, May 23, of a self-inflicted gunshot wound and coronary thrombosis

Samuel Wolfe, Philadelphia University of Pennsylvania Department of Medicine, Philadelphia 1873, member of the House of Delegates of the American Medical Association, 1907-1910, emeritus professor of theory and practice of medicine and clinical medicine at the Temple University School of Medicine, formerly on the staffs of the Samaritan, Old Blockley and the Garretson hospitals, aged 85, died April 28 in Daytona Beach Fla

James A. Foltz Ⓢ Fort Smith, Ark., Tulane University of Louisiana Medical Department, New Orleans, 1901, past president of the Sebastian County Medical Society, fellow of the American College of Surgeons, on the staffs of the Sparks Memorial Hospital and St. Edward's Mercy Hospital, veteran of the Spanish-American War, formerly member of the city board of education and board of health, aged 59, died, May 22, of heart disease

Lee Bey Greene Ⓢ Edgeley, N. D., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905, served during the World War, member of the state board of medical examiners, past president of the La Moure County Medical Society, aged 56, died, May 3, in the Northern Pacific Hospital, St. Paul

John Leonard Chester Ⓢ Detroit, Saginaw (Mich.) Valley Medical College, 1900, associate professor of clinical medicine at the Wayne University College of Medicine, past president of St. Clair County Medical Society, on the staffs of the Eloise (Mich.) Hospital and the Providence Hospital, fellow of the American College of Physicians, aged 69, died, May 31

Augustine Mathias Zell, Little Rock, Ark., Washington University School of Medicine, St. Louis, 1905, member of the American Roentgen Ray Society and the Radiological Society of North America, formerly instructor in electrotherapeutics at the University of Arkansas School of Medicine, aged 54, was found dead, April 23, of an accidental gunshot wound

Walter Edgar Barber, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1913, member of the Medical Association of Georgia, past president of the Fulton County Medical Society, formerly on the staffs of the Grady, Emory University, Crawford W. Long Memorial and the Georgia Baptist hospitals, aged 52, died May 24, of coronary thrombosis

Robert Rodney Dale Ⓢ Texarkana, Ark., University of Virginia Department of Medicine Charlottesville, 1913, fellow of the American College of Surgeons, on the staff of the

Michael Meagher Memorial Hospital, aged 52, died, May 10, in the Army and Navy General Hospital, Hot Springs National Park, of chronic interstitial nephritis

Garfield McCoy Hackler, Dallas, Texas, University of Maryland School of Medicine, Baltimore, 1891, professor of clinical surgery at Baylor University College of Medicine, member of the State Medical Association of Texas, fellow of the American College of Surgeons, on the staff of the Baylor Hospital, aged 72, died, May 6

Alfred Harrold Thomas, Staten Island N. Y., Yale University School of Medicine, New Haven, 1898, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, served during the World War, aged 62, on the staff of the Staten Island Hospital, where he died, April 15, of pneumonia

Wilbur Henry Rietz Brandenburg Ⓢ Washington, D. C., Columbian University Medical Department, Washington, 1903, for many years a member of the board of police and fire surgeons, aged 59, died, May 11, in the George Washington University Hospital of atrophy of the liver and toxic nephrosis

Emma Louisa Call, Cambridge, Mass., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1873, member of the Massachusetts Medical Society, aged 89, at one time attending physician to the New England Hospital for Women and Children, Boston, where she died, May 3

Richard Lounsbury Eltinge, Mendota, Wis., New York Homeopathic Medical College and Hospital, 1901, member of the American Psychiatric Association, on the staff of the Veterans Administration Facility, served during the World War, aged 61, died, May 21, of coronary thrombosis

Michael Waldon Conway Ⓢ Elma Wash., College of Physicians and Surgeons, Los Angeles, 1917, past president of the Grays Harbor County Medical Society, served during the World War, medical director of the Conway Hospital, aged 53, died, May 18, of coronary thrombosis

Rolla Baxter Stafford Ⓢ Topeka, Kan., University Medical College of Kansas City, 1901, formerly health commissioner of the Virgin Islands, and health officer of Brown County, member of the state board of health, aged 58, died, April 26, in Christ's Hospital, of thrombosis

Isadore Henry Cramer, Portland, Ore., Denver and Gross College of Medicine, 1909, member of the Oregon State Medical Society, served during the World War, aged 50, died, May 2, in the Good Samaritan Hospital, of hypertensive cardiovascular renal disease and uremia

Lawrence Parker Conley, Clifton Springs, N. Y., Cleveland University of Medicine and Surgery, 1897, member of the Medical Society of the State of New York, county coroner, village health officer and health officer of the town of Hope-well, aged 63, died, May 10

Julian Arthur Du Bois Ⓢ Sauk Center Minn., Rush Medical College, Chicago, 1879, an Affiliate Fellow of the American Medical Association, formerly mayor, aged 81, died, May 4, of cerebral hemorrhage, carcinoma of the stomach and hypertrophy of the prostate

Lyman Bon Bacon, Westboro Mass., Western Reserve University Medical Department, Cleveland, 1882, member of the Iowa State Medical Society, aged 77, died, May 14, in the Memorial Hospital, Worcester, of hypertrophy of the prostate and arteriosclerosis

William Samuel Emberson, New Rochelle, N. Y., New York University Medical College, 1898, member of the Medical Society of the State of New York, consulting surgeon to the New Rochelle Hospital, aged 62, died suddenly, May 17, of coronary occlusion

Lyman Trevitt Wade, San Luis Obispo, Calif., Bennett College of Eclectic Medicine and Surgery, Chicago, 1888, member of the California Medical Association, aged 70, died, April 11, of cerebral hemorrhage, hypertension and arteriosclerosis

Louis Philippe Gaillardet, Fairchild, Wis. (licensed in Wisconsin in 1900), formerly a member of the board of health in Kansas and city health officer and county physician in Black River Falls, aged 78, died, April 14, of cerebral hemorrhage

George Alonzo Cryer, Anniston, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1903, member of the Medical Association of the State of Alabama, served during the World War, county health officer, aged 59, died, May 23

John Cabean Caldwell, Chester, S. C., University of Maryland School of Medicine, Baltimore, 1914, member of the South Carolina Medical Association, and state board of medical examiners, aged 47, died, May 10, of carcinoma of the liver

Frank Butler Clark, Ganesboro, Tenn, University of Nashville Medical Department, 1911, member of the Tennessee State Medical Association, county health officer, aged 53, died, May 7, in a hospital at Livingston, of cerebral hemorrhage

John Grace, Belleville, Ark., Vanderbilt University School of Medicine, Nashville, Tenn, 1893, member of the school board and formerly a member of the county board of education, aged 69, died, May 24, in a hospital at Russellville

Harris Hartwell Bass Sr, Henderson, N C, University College of Medicine, Richmond, 1899, member of the Medical Society of the State of North Carolina, aged 59, died, May 18, of coronary thrombosis and carcinoma of the pancreas

Finley Ransom Cook, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895, member of the Medical Society of the State of New York, aged 68, died, May 5, in Hawthorne

William Middleton Duke, Minter City, Miss, Memphis (Tenn) Hospital Medical College, 1901, member of the Mississippi State Medical Association, aged 56, died, May 26, of diabetes mellitus and pulmonary tuberculosis

Stephen Vincent Cotter Ⓢ Buffalo, St Louis University School of Medicine, 1920, member of the Radiological Society of North America, on the staff of the Mercy Hospital, aged 43, died, May 30, of coronary thrombosis

Harman Richard Townsend Ⓢ Oakville Tenn Vanderbilt University School of Medicine, Nashville 1912, on the staff of the Oakville Memorial Sanatorium, aged 51, was drowned April 14 in the Mississippi River

Ambrose Kirk Brennan, Plainfield, N J, Yale University School of Medicine, New Haven, Conn, 1893, aged 66, on the staff of the Muhlenberg Hospital, where he died May 24, of carcinoma of the transverse colon

Rinaldo Everett Baker, Boise, Idaho, Kansas City (Mo) Hahnemann Medical College, 1912, served during the World War, aged 61, on the staff of the Veterans Administration Facility, where he died, May 1

Theodore Elliott Collier, Brook, Ind, Medical College of Indiana, Indianapolis, 1893, for many years a member and at one time president of the board of education, aged 74, died, May 29, of multiple sclerosis

Anthony Crocicchia, New London, Conn, Regia Università degli Studi di Roma Facoltà di Medicina e Chirurgia, Italy, 1893, aged 69, died, May 2, in Waterbury, of carcinoma of the bladder and prostate

Asa Douglass Campbell, Shaker Heights, Ohio, Northwestern Ohio Medical College, Toledo, 1888, formerly on the staff of the Glenville Hospital, Cleveland, aged 81, died, May 8, of lobar pneumonia

Alfred C Drouillard, Wyandotte, Mich, Detroit College of Medicine, 1893, for many years president of the board of education and school physician, formerly city health officer, aged 73, died, May 23

Charles Becker, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1893, served during the World War, aged 68, died, May 12, in the Presbyterian Hospital of prostatic hypertrophy

James D Mooney, Crystal Springs, Miss (licensed in Arkansas in 1903) member of the Arkansas Medical Society formerly mayor of Coal Hill, Ark., aged 69, died, April 30, at Lone Pine, Ark

Philip H Cosner, Newark, Ohio, Baltimore Medical College, 1896, past president of the Licking County Medical Society, aged 66, died, May 5, in the Licking County Tuberculosis Sanatorium

Frank Anthony Gravino, New York, Long Island College Hospital, Brooklyn, 1935, resident surgeon to the Bronx Eye and Ear Infirmary, aged 26, was killed, May 7, in an automobile accident

Holly M Baxter, Bohon, Ky, Kentucky School of Medicine, Louisville, 1898, member of the board of education, aged 64, died May 19, in the Good Samaritan Hospital, Lexington, of pneumonia

Harold Fonseca Da Costa, Chicago, Loyola University School of Medicine Chicago 1922 member of the Illinois State Medical Society, aged 46, died, May 23, of coronary thrombosis

James Bennett Gildee, Lowell, Mass, Bellevue Hospital Medical College New York, 1880, aged 79, died May 13, in St Johns Hospital, of diabetes mellitus and gangrene of the right leg

Erle Will Zook, Peoria, Ill, Rush Medical College, Chicago, 1895, aged 64, formerly on the staff of the Peoria State Hospital, died, April 7, of pneumonia following a sinus infection

Pleasant E Terry, Holly Grove, Ark, Memphis (Tenn) Hospital Medical College, 1899 member of the Arkansas Medical Society, aged 63, died suddenly, April 29, of coronary sclerosis

Malcolm McLachlan Crawford, Toronto, Ont, Canada, University of Toronto Faculty of Medicine, 1898, chief coroner of Toronto and supervising coroner for Ontario, aged 57, died, May 14

Thomas B Blakely, Coal Hill, Ark, Arkansas Industrial University Medical Department, Little Rock, 1883, aged 78, died, May 17, of carbuncle of the neck and erysipelas

John W Aldridge, Evansville, Ind, University of Tennessee Medical Department, Nashville, 1891, aged 79, died May 4, of chronic nephritis and carcinoma of the hip

Edward Erle Brownell, San Francisco, Johns Hopkins University School of Medicine, Baltimore, 1899, aged 62, died, May 3, of bronchopneumonia and chronic bronchitis

Isaac H Reiley, New York, College of Physicians and Surgeons of Chicago, 1884, member of the Medical Society of the State of New York, aged 93, died, April 30

Frederick E King, New Milford, Conn, University of Buffalo School of Medicine, 1876, formerly health officer of New Milford, aged 82, died, April 5

Thomas Ervin Anderson, Carthage, Texas, Vanderbilt University School of Medicine, Nashville, Tenn, 1913, aged 48, died, May 6, of angina pectoris

J W Hunter, Pax, W Va (licensed in West Virginia in 1884), formerly a member of the state legislature, aged 83, died, April 26, of acute nephritis

Lucius Bradley Dorr Ⓢ Buffalo, University of Maryland School of Medicine, Baltimore, 1890, aged 71, died suddenly, May 5, of cerebral hemorrhage

William Edgar Brunson, Sherrill, Ark (licensed in Arkansas in 1903), aged 59, died, May 31, in a hospital at Pine Bluff, of lobar pneumonia

Richard Emmett Thacker, Oklahoma City, Kansas City (Mo) Medical College, 1898, aged 64, died suddenly, April 1, in McAlester, of heart disease

John Christian Eigenmann, Springfield, Ill, Northwestern University Medical School, Chicago, 1897, aged 65, died, May 10, of malignant teratoma

Harry Brawley Bailey, Rockford, Ill, Rush Medical College, Chicago, 1902, aged 59, died, May 7, in McAllen, Texas, of coronary thrombosis

Robert A Gilmore, San Diego, Calif, L R C S, L R C P, Edinburgh, Scotland, 1879, formerly a practitioner in Omaha, aged 80, died, May 2

Luis Fernandez Alvarez Ⓢ Los Angeles, Cooper Medical College, San Francisco, 1887, aged 84, died, May 24, of bronchopneumonia

David Kenneth Stenton, St Thomas, Ont, Canada, Western University Faculty of Medicine, London, 1890, aged 78, died, April 12

Joseph L Barker, Dearing, Kan, Kansas City (Mo) Medical College, 1887, aged 73, was found dead in bed, May 9, of angina pectoris

Franklin Worthington Bush, Hannibal, Mo, Missouri Medical College, St Louis, 1876, aged 86, died, May 19, of arteriosclerosis

David Morgan Addington, Sutter, Calif, University of California Medical Department, San Francisco, 1879, aged 84, died, May 7

Jessie Beaumont Atkins, Clarksville, Tenn, Hering Medical College, Chicago, 1896, aged 73, died, May 13, of cerebral hemorrhage

Cleveland Roy Wilson, Toronto, Ont, Canada University of Toronto Faculty of Medicine, 1911, aged 49, died, April 19

Ralph Pern Gaskill, Columbus, Ohio, Ohio Medical University, Columbus, 1903, aged 57, died, May 3, of chronic myocarditis

Park McConnell Gilmore, Covington, Ky, Miami Medical College, Cincinnati 1903, aged 56, died, May 13, of heart disease

Bureau of Investigation

DR J L STATLER AND NORMAN BAKER

Federal Communications Commission Denies
Application of Baker Hospital Lessee to
Maintain a Radio Broadcast Studio
at Muscatine, Iowa

The application of J L Statler, doing business as Baker Hospital, Muscatine, Iowa, for authority to transmit programs to stations in Canada and Mexico has been denied by the Federal Communications Commission. The order was entered on June 1, 1937, effective at 3 a m eastern standard time Aug 3, 1937.

The commission held that the "public interest, convenience and necessity will not be served by granting application" for authority under section 325 to transmit programs to foreign stations.

The applicant, Dr Statler, is a long-time associate of Norman Baker and lessee of the Baker Hospital. The history of Norman Baker and the Baker Hospital is well known to the medical profession. Baker and his alleged cancer cure were dealt with editorially in *THE JOURNAL* of April 12, 1930, page 1146, and April 19, 1930, page 1241, and in *Hygeia* for May 1930, page 418, and by the Bureau of Investigation in *THE JOURNAL* for March 19, 1932, page 1012.

As a result of *THE JOURNAL*'s expose of Baker's activities, he brought suit against the Association, asking one-half million dollars in damages. The case went to trial on Feb 9, 1932, and terminated on March 3, when the jury returned a verdict for the American Medical Association.

Prior to entering the quack cancer field, Baker had sold radio sets, storage batteries, flour, coffee, canned fruit, silverware, brooms, alarm clocks, overcoats, mattresses, automobile tires, typewriters and general merchandise. In addition to printed catalogues and his magazine *T N T* (The Naked Truth), Baker also advertised his wares over his radio station, KTNT of Muscatine.

Station KTNT, operated by Norman Baker, was ordered off the air by the Federal Radio Commission June 5, 1931. In taking this action, it was reported, the commission sustained the recommendation of its chief examiner, who found that Baker used the station as a "private mouthpiece" in promoting business interests in which he was engaged, these were some twelve enterprises in Muscatine, including a newspaper and a mail-order business. Moreover, he used his station in attacking the medical profession and other individuals and organizations not in agreement with him.

After KTNT was banned from the air, Baker opened a powerful new station, XENT, near Nuevo Laredo, Mexico. This station was licensed by the Mexican government to operate with 150,000 watts. It is one of the strongest stations on the North American continent.

Feb 14, 1935, Baker applied to the Federal Communications Commission for a permit to open a new broadcasting station in Muscatine. His application was denied.

Among the Baker associates in the cancer hospital enterprise was one Johnson Lewis Statler, a graduate of Barnes Medical College, St Louis, 1909. The Federal Communications Commission, in denying the Statler application to maintain a radio broadcast studio at Muscatine for the purpose of making transcriptions to be transmitted to stations in Canada and Mexico, was constrained to find that the applicant (Statler) was not the real party in interest in the case.

A recent decision of the Supreme Court of the State of Iowa (*State v Baker* 270 N W 359, decided Dec. 15, 1936) found Norman Baker guilty of contempt for violating, through the fiction of a lease of the Baker Hospital to Dr J L Statler and others, an order enjoining him from practicing medicine in the State of Iowa.

According to the Federal Communications Commission's report of the hearing, "The only evidence offered by applicant with respect to a need for the proposed service related to the falling off of business of the Baker Hospital when KTNT was deleted."

The monthly receipts from Baker's cancer-cure activities started at \$1,380 for October 1929, climbed to \$75,232 for June

1930, and, following the articles published by the American Medical Association, dwindled until in January 1932 he took in only \$7,008.

On April 22, 1937, Norman Baker was sentenced by Federal Judge Thomas M Kennerly, presiding in the District Court of the United States for the Southern District of Texas, to four months in jail and to pay a fine of \$2,000 to the United States of America, "for conspiracy to locate, maintain and use apparatus from which and whereby sound waves are and were converted into mechanical and physical reproductions of sound waves and to carry, transport and deliver to a radio broadcast station in a foreign country for the purpose of being broadcast from that station and which said station was so located geographically that its emissions were received consistently in the United States, without first obtaining a permit from the Federal Communications Commission."

In turning down the Statler application, the Federal Communications Commission said "It is our opinion that the applicant has failed to show that the program service proposed to be rendered [advertising the Baker Hospital] would be in the public interest."

Which is putting it mildly!

GERMANIA HERB TEA

Companies Exploiting Purgative Reducing Nostrum
Receive Federal Trade Commission Cease
and Desist Order

The Federal Trade Commission has ordered the Germania Tea Company, 608 First Avenue North, Minneapolis, and the Consolidated Drug Trade Products, Inc, 544 South Wells Street, Chicago, to stop representing that "Germania Herb Tea" performs any functions in a reducing program other than those of a laxative or purgative, and that "Germania

Orange Pekoe Tea" performs any function or has any value in treating obesity, or in a reducing program, other than in the caffeine supplied through its consumption.

According to a report of the Federal Trade Commission dated June 18, 1937, the principal ingredients of Germania Herb Tea are senna, which has laxative and purgative qualities, and jumper, a diuretic, and the principal ingredient of Germania Orange Pekoe Tea is caffeine.

Germania Tea was the subject of an article in *THE JOURNAL* April 8, 1933, page 1126. A few months later (Sept 9, 1933, p 870) *THE JOURNAL* reported that a quantity of Germania Herb Tea shipped by the Royal Drug Company of Chicago was the subject of a Notice of Judgment issued by the Food

and Drug Administration, which declared that the product bore fraudulent therapeutic claims on the label.

The current Germania Herb Tea advertising continues to play up a Margaret George, who, it is stated, lost 62 pounds of "ugly fat." The George person, the advertising states, is "now employed giving free demonstrations."

Germania Herb Tea is sold "At All Drug and Department Stores." Stores selling this nostrum would better serve their customers if they informed the obese that the persistent and indiscriminate use of purgatives as a means of reducing weight is an extremely dangerous procedure. Hurrying food through the bowel before proper assimilation takes place must ultimately result in a badly irritated digestive apparatus and a series of concomitant secondary alimentary derangements.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ORAL DESENSITIZATION TO HAY FEVER

To the Editor—I understand that there are favorable reports concerning the use of the oral administration of ragweed pollen. Can you give me references in the literature and state where the material can be procured?

WARD E. COLLINS, M.D., Kalamazoo, Mich.

Is it true that there is a desensitizing agent available which can be taken by mouth? If there is, will you please advise me who manufactures it?

FRANK R. MAURER, M.D., Cicero, Ill.

I have seen an article in the medical column of the newspapers on "Hay Fever Vaccines by Mouth." Would you advise general practitioners to treat hay fever in this manner?

M.D., Iowa

ANSWER—Touart (*New York M. J.* 116:199 [Aug. 16] 1922) treated six hay fever patients by daily ingestion of a phenyl salicylate coated tablet containing 0.1 mg. of pollen protein. While those who were sensitive to grass pollens obtained relief only, one out of the six ragweed patients was benefited. Black (*J. Lab. & Clin. Med.* 12:1156 [Sept.] 1927), experimenting on himself, found that ragweed antigen could be demonstrated in the blood and urine after the ingestion of large amounts of ragweed pollen extract. Subsequently (*J. Lab. & Clin. Med.* 13:709 [May] 1928) he used oral therapy in a number of grass or ragweed sensitive patients. Complete failures occurred in 20 per cent with oral therapy as against 6 per cent with the injection method. In pollen asthma oral therapy failed completely in 22.2 per cent while with the hypodermic therapy no complete failures were noted.

Thommen (Asthma and Hay Fever in Therapy and Practice, Springfield, C. C. Thomas, 1931, p. 764) cites a satisfactory result in one case with oral pollen therapy but such attempts in other cases gave variable results. Thommen mentions as disadvantages the large amounts of extract required and the variability of enteral absorption by oral administration of specific peptones. Urbach (*Klin. Wchnschr.* 10:534 [March 21] 1931) succeeded in alleviating the symptoms of a man sensitive to the pollen of the horse chestnut by the oral use of the pollen peptone of the latter. Later he (*Wien. klin. Wchnschr.* 47:1073 [Aug. 31] 1934) wrote more broadly of this type of pollen therapy. He later (*Klin. Wchnschr.* 12:1797 [Nov. 18] 1933) reported similar results by the use of peptones made from the entire pollinating flower.

In 1933 Gatterdam (*Southwest Med.* 17:199 [June] 1933) reported on oral pollen therapy which subject he elaborated in 1934 (*ibid.* 18:130 [April] 1934). In his series of eighty-five hay fever patients treated with pollen orally from 75 to 85 per cent were markedly relieved. He stated further that "where results are not obtained by oral administration alone it can be used as an adjunct along with parenteral injections." The doses were given twice daily with additional doses for attacks. The usual amount used was from three to fifteen drops of the 3 per cent extract diluted in one-fourth glass of water. Mild urticaria or hay fever reactions occasionally resulted from overdosage. The pollens used were cottonwood, ash, Bermuda grass, rabbit bush and the false ragweeds.

The fact that a number of hay fever sufferers had stated that they obtained relief by the eating of honey produced in their vicinity led McGrew (*Mil. Surgeon* 80:371 [May] 1937)

to suspect that the pollen in the honey was responsible for the result. He therefore instituted oral pollen therapy. The average dose was four drops of a 1 per cent extract three times daily. Excessive doses caused aggravation of symptoms. Of thirty-three patients thus treated, twenty-nine were improved. Those with multiple allergy or with asthma did not do well.

Urbach (*München med. Wchnschr.* 84:488 [March 26] 1937) reported coseasonal treatment with proteins of the appropriate grass, grain or flowers (not the pollens, though these were used for testing). Good results are claimed.

Bernstein and Kirsner (*J. Allergy* 8:221 [March] 1937) in a recent paper on experimental considerations of oral pollen therapy attacked the problem by passive transfer of blood serum from patients with ragweed hay fever to normal skins. Five grains (0.3 Gm.) of ragweed pollen was then given by mouth to these subjects and no positive skin test occurred at the sensitized sites; this demonstrates that enteral absorption of pollen in the dosage used is so slight as to be nondetectable by passive transfer. They also showed that peptic digestion of ragweed pollen, either whole or as extract, does not destroy its activity. This is important as indicating that pollen may be given by mouth without destruction by the gastric juices. This does not agree, however, with the observations of Moore and Unger (*J. Allergy* 5:338 [May] 1934) who found that pepsin and papain digested timothy and short ragweed pollen to such an extent as to lessen materially the activity of the pollen extract. Bernstein and Kirsner also pointed out that the pollen therapy by mouth has the disadvantages of greater expense of too great a variability of intestinal absorption and of inability to observe local reactions in the matter of dosage.

Finally Stier and Hollister (*Northwest Med.* 36:166 [May] 1937) observed 383 cases extending over three years and found that the oral administration of pollen extracts gave about as good results as were obtained by the hypodermic method. They emphasized the ease of administration of the oral method and the wider margin of safety and stated that coseasonal treatment was as effective as preseasonal. Their data were obtained largely by the questionnaire method.

Practically all these reports emanate from the Northwest, Southwest or Europe—localities where ragweed is not an important offender. The latest and most complete favorable report (Stier and Hollister) is apparently based on the doubtful reliability of the questionnaire method. The few reports in the ragweed areas are not especially favorable. Self-administered therapy, unless thoroughly supervised by a physician, is likely to lead to many difficulties.

Pollen for oral use has not yet been placed on the open market by any recognized pharmaceutical house. This form of therapy for hay fever is still experimental and unproved. It would seem wise to await further reports from recognized experts in the field of allergy.

SENSITIZATION TO MILK AND PSYCHIC AVERSION TO MILK

To the Editor—A recurring problem in a practice of many years has often been what to do with those innumerable patients who say they can not take milk. Calcium deficiency is certainly prevalent enough. I think that many of us would appreciate a discussion from some authoritative source of this continually recurring subject.

FREDERICK J. WALTER, M.D., San Diego, Calif.

ANSWER—It is true that, while milk modification for infant feeding has been extensively studied, milk modification for the adult has had but little attention paid to it. There may be four different causes for a person's assertion that he cannot take milk. It may be due to erroneous interpretation of digestive disturbance, to allergy, to inherent difficulty in digesting milk, or to purely psychic aversion.

Characteristic of erroneous interpretation of digestive difficulty is the heterogeneous array of foods that the patient claims disagree with him and the fact that at one time he can take these foods without the distress which is produced by them at some other time. This condition, typically encountered with patients afflicted with cholecystitis or with spastic colon, is best treated by urging the patient to eat everything as it is, not the particular food just then eaten that caused the distress, but the fact that it was taken at a time when the taking of any food would have been distressful, because of the disturbance set in motion by the underlying disease.

When milk always disagrees, whenever it is taken, even in small quantity, this may be due to milk allergy, and, especially, if the total aspect of the case renders allergy probable, testing the skin reaction to milk proteins and test diets permits a conclusion as to the presence or absence of this specific allergy. When hypersensitiveness to milk is present, it is generally more practical to eliminate milk from the dietary completely rather than to attempt desensitization.

When the patient experiences inherent difficulty in milk digestion, the nature of this difficulty must be discovered. When milk is well digested it is a constipating food, when not, it produces diarrhea. This condition can generally be remedied by having the patient take boiled skimmed milk. When milk is constipating, adding cream to it or the use of liquid petrolatum will antagonize this tendency. When gastric distress is experienced every time milk in quantity is taken, this is probably due to coarse curdling of the milk. Boiling the milk lessens the size of the curd. The size of the curd is furthermore lessened by diluting the milk with an equal amount of water or, better, with carbonated water or barley water. A mixture of equal parts of cream and seltzer water may be relished and well digested. The addition of lime water is especially useful when milk produces diarrhea. The addition of sodium citrate (from 1 to 2 per cent) lessens the size of the curd and it also antagonizes somewhat the constipating tendency of milk and emphasizes its diuretic quality. The addition of large quantities of other fluid to the milk has the disadvantage of still further diluting this naturally bulky food. Hence the importance of insisting on sipping the milk and mixing it with saliva, which dilutes the milk with alkaline fluid without adding to the store of fluid in the system. One method of insuring the proper ingestion of milk is to have it chewed with cracker. The best way of preventing the formation of large curds, however, is to curdle the milk before giving it. This is why buttermilk, koumiss, matzoon or junket is often better digested than unmodified milk.

The person who has psychic aversion to milk is best served by disguising the milk, which can be done in innumerable ways. Adding it or cream to coffee, tea or cocoa is one way. Clams or oysters may be used to flavor the milk, which may be eaten either with or without them. Making various milk soups out of it is another. The various "infant foods," such as "malted milk," help by adding flavor as well as nutriment. Cereal gruels or toast taken with milk or cream and sugar to taste, are usually liked and well digested. "Milk punches" and egg nogs of various types are delectable. So are ice creams, ice cream sodas and so-called sundaes.

One may conclude, therefore, that unless a person has milk allergy it is merely lack of understanding and skill that makes impossible the giving of milk to a person who needs it.

ALCOHOL INJECTIONS IN CARCINOMA OF VERTEBRAE

To the Editor—I have under treatment a woman who has a metastatic carcinoma of the eleventh and twelfth dorsal vertebrae. Recently she has developed pain along the course of the right ilio-inguinal nerve. A therapeutic spinal anesthesia between the twelfth dorsal and first lumbar vertebrae gave marked but passing relief. Somewhere in my reading I have seen an article on the use of alcohol in these cases for more permanent relief. Please send all information and references on this subject available.

M D Iowa

ANSWER—The use of intraspinal alcohol injections for the relief of pain in cases of carcinoma has been considerably practiced, but there is no question that it is a delicate and dangerous procedure and unless strict attention is paid to the details of technique the patient may be more injured than helped.

In general, the use of a moderate amount of carefully measured x-rays, say 300 roentgens given twice a week for a period of about a month and then repeated after an interval of a month, will result in more satisfactory relief from pain than do the alcohol injections.

There are a number of excellent papers on the subject of alcohol injections, among them one by Ritchie Russell in the *Lancet* (1595 [March 14] 1936) and another by E. L. Stern in the *American Journal of Surgery* (25:217 [Aug.] 1934). Russell's directions are as follows: The patient must lie with the side of the body in which most pain is felt uppermost and in the usual semirecumbent posture employed for lumbar puncture. The operating table is tilted so that the sacrum forms the highest part of the spine, and the head should always be kept lower than the spine. The lumbar puncture should be made between the third and fourth vertebrae. A few cubic centimeters of spinal fluid is allowed to escape and 0.4 cc of absolute alcohol is slowly injected, the whole amount being introduced during a period of about twenty seconds. Cerebrospinal fluid should not be drawn into the syringe prior to injection. The patient is made to lie in the same position for about an hour and must on no account raise his head or the upper part of his body. He may, however, with advantage turn slightly on his face as soon as the injection is completed so that the alcohol may have access more to the posterior than to the anterior nerve roots. After lying in the same position for about an hour the patient is treated as for an

ordinary lumbar puncture. Headache after injection is rare. In some cases the pain disappears at once, in some it remains unchanged for several days and then ceases, in some it becomes less but is not abolished. If the pain is still severe ten days after the injection, the operation may be repeated. For lumbar or thoracic pain the injections may be made between the second and third lumbar vertebrae. In nervous cases morphine and scopolamine should be given before injection. A list of references is included in Russell's paper.

Stern in his article calls attention to the necessity of using alcohol sterilized by boiling. He says that the patient should be turned flat on his back ten minutes after the injection has been made and the foot of the bed elevated from 4 to 8 inches. The patient should be kept in this position for two hours, well covered and protected from drafts, but should not sit up until four hours after the injection and should remain in bed for at least twenty-four hours. Catheterization may be necessary. Sedatives should be used liberally to relieve postinjection reactions such as headache or pain. If the patient is not relieved after five or six days, the injection can be made one or two segments above or below the level first injected, depending on the segment affected, as shown by skin tests. The needle should never be inserted above the first thoracic vertebra. Stern states that when successful the procedure may relieve pain for as long as eight months and allows more intensive x-ray, radium or other medical treatment to be given and so tends to prolong life.

BUFFERING EYE SOLUTIONS

To the Editor—Kindly send me detailed information with regard to the procedure to buffer the eye solutions according to formulas of Dr. Sanford Gifford to adjust the pH of solutions. Also I am interested in knowing the practical procedure to make eye solutions isotonic. I have a copy of 'A Ready Method for the Extemporaneous Preparation of Isotonic Collyria' by Mellen and Seltzer (*J. Am. Pharm. A.* September 1936) and a copy of 'The Art of Compounding' by W. L. Seaville (ed. 5 Philadelphia: P. Blakiston's Son & Co. 1927) but I want if possible further and more detailed information. Is there a practical procedure to make eye solutions isotonic and with the correct pH at the same time?

RICARDO GALDIS M.D. Havana, Cuba

ANSWER—A method for adjusting the pH of solutions was described by Gifford in the *Archives of Ophthalmology* (13:78 [Jan.] 1935). It consisted in the preparation of an acid buffer solution of pH 5, which was made more alkaline by the addition of small amounts of a stock solution of sodium carbonate. The acid buffer solution contained boric acid (powdered) 12.4 Gm, potassium chloride (anhydrous) 7.4 Gm and distilled water 1000 cc. The stock sodium carbonate solution contained sodium carbonate (anhydrous) 21.2 Gm and distilled water 1000 cc. When 0.05 cc of the latter solution is added to 30 cc of acid buffer solution, the reaction of the solution is pH 6. When 0.1 cc is added to 30 cc, the pH is 6.2. When 1 cc is added, the pH is 7.2. When 1.5 cc is added, the pH is 7.6. When 3 cc is added, the pH is 8.2. When 4 cc is added, the pH is 8.4. When 8 cc is added, the pH is 9.

It seemed that reaction was much more important as to reactions produced than tonicity. With the small amounts of alkalis used in eye-drops a solution in 0.9 per cent sodium chloride would be practically isotonic. It is not obvious how the pH of a solution could be changed while keeping it isotonic without very complicated changes in buffer solutions for each prescription.

IMMUNIZING DOGS TO RABIES

To the Editor—Enclosed is a reprint concerning the prophylaxis of rabies in dogs and although *Queries and Minor Notes* of *The Journal* for April 3 carried a question and answer concerning this matter I am still not satisfied. I own a pet dog and have been under the apparent delusion that the one shot vaccine was sufficient prophylaxis against rabies. I should like an opinion regarding this matter.

M D Louisiana

ANSWER—There is no question that preventive vaccination against rabies in the dog is still strictly in the experimental stage. Obviously, compulsory vaccination of dogs should not be urged as long as absolutely reliable and safe methods of vaccination are not available. In the meantime there must be no relaxation but rather more strict enforcement of the only available methods of preventing canine rabies, namely, licensing and quarantining, and impounding and killing stray dogs.

As to the merits of the article mentioned in the question (*The Rabies Racket*, by Dr. William A. Bruette in the May 1937 issue of *House and Garden*), it may be said that its attack on the one shot rabies vaccine is well founded and timely because there is no evidence that such vaccination prevents rabies. But the explanation offered to account for symptoms

in so-called mad dogs is not wholly acceptable, because it tends to belittle the dangers of dog bites to human beings. A dog with such symptoms—excitement, restlessness, fits—may be rabid and should be treated as dangerous. The possibility of rabies from dog bite under any circumstance should never be minimized. *THE JOURNAL* (Aug. 8, 1936) pointed out editorially that the least that can be done is to cauterize the wound and place the dog under observation for three weeks to rule out rabies. If the dog cannot be found or identified, the safest course is to give antirabic treatment. The article is on safe ground in advocating the destruction of homeless dogs and quarantine as the only reliable means of controlling canine rabies. There is great need of intelligent public support of such efforts by officials. Recently a dog found to be rabid bit seven children in a Chicago school, in 1936 six persons died of rabies in Chicago, and it appears that the total number of persons bitten by dogs in that city is increasing. The article is probably not on wholly safe ground when it asserts that rabies in this country is on the increase as the result of infection from rabies vaccine, account should be taken of the fact that in nature the frequency of rabies fluctuates much.

PEDIATRIC DIAGNOSIS

To the Editor—I have had under observation for the past two months a boy aged 3 years who returned to the office today with a chronic complaint of occasional pain in the right axilla. Physical examination revealed impaired resonance and diminished breath sounds over the right lower lobe of the lung and a harsh systolic murmur over the precordium. During the examination his face became flushed, his eyeballs seemed to roll upward, and he became somewhat stuporous for a few minutes. His afternoon temperature was 99.2 F. The remainder of the examination was negative, the child being well nourished and well developed and having recorded a 2 pound gain in weight the past three weeks. The mother states that the child becomes listless and tired in the afternoon and undergoes the vasomotor changes about once daily. The patient was first seen by me two months ago at his home. He had a temperature of 104 and complained of pain over the right lower lobe. Respirations were increased but not labored. Epistaxis occurred while I visited him. Physical examination revealed a friction rub over the right lower lobe. The following day his temperature was normal but for several days thereafter continued to be of low grade with occasional epistaxis. The urine examination was negative. The ears were normal. He was discharged ten days after the onset of the disease with orders to stay in bed one more week. Two weeks later I was called to the house and his symptoms were the same as originally. However he had a loose cough and was expectorating some mucoid material. He was sent to the hospital for further study and x-ray examination of the chest. Blood and urine studies were negative. He was discharged from the hospital one week later with a normal temperature. Forceful questioning of the mother brought out the fact that the child's aunt had tuberculosis a year ago. With this complexity of symptoms and negative laboratory studies I am at a loss as to how to proceed further. Do you think it is advisable to repeat the x-ray examination? I would appreciate any suggestions as to diagnosis and further procedure. Please omit name and address.

M D, Wisconsin

ANSWER—The query presents a 3 year old patient with a number of symptoms that are difficult to unravel. The physical examination reveals impaired resonance and diminished breath sounds over the lower lobe of the right lung. These signs might indicate pleural effusion, collapse of the lung, infiltration of the parenchyma of the lung with an occluded bronchus, an elevation of the diaphragm due to abdominal distention, or enlargement of the liver causing pressure from below.

On another examination, friction sounds were heard over the lower lobe of the right lung. In addition, there was a productive cough. In spite of all these suggestive symptoms, the x-ray examination of the chest did not reveal lung changes.

A harsh systolic murmur was heard over the heart area, though no mention is made of the size of the heart, location of the apex beat, presence or absence of thrill, rate or rhythm of the heart beat, whether the heart tones were strong or feeble, or whether there was an accentuation of one or the other tone. The importance of these observations is obvious. In the interpretation of a harsh systolic murmur over the precordium, the question arises: Could the patient possibly be suffering from a congenital or acquired heart lesion?

It is further recorded in the query that during the examination of the patient his face became flushed, the eyeballs seemed to roll upward, and he became stuporous for a few moments. Could these symptoms indicate a mild convulsive seizure, which is commonly called petit mal? Was the attack possibly due to a heart block producing an Adams-Stokes syndrome? We would suggest investigating the patient carefully on this score and also for a cerebral involvement to elucidate the possible cause of the convulsions. An electrocardiographic study would show whether there is any evidence of heart block.

It is also mentioned that the patient had epistaxis on several occasions. The most common cause of epistaxis in children

is ulceration of the nasal septum or a varicosity of the veins of the nasal mucosa. It also occurs in severe rhinitis. It is observed in conditions that cause high venous blood pressure, such as bronchitis, emphysema or heart disease causing dilatation of the right side of the heart, though in any case the local condition of the nose should be ascertained by thoroughly illuminating the nasal mucosa with mirror and reflected light.

Finally, the query mentions the fact that a member of the family had suffered from tuberculosis, and we infer that the child may have been exposed to this disease. In order to remove any doubt about tuberculosis in the child, one should make a skin tuberculin test, such as a Mantoux or Pirquet. If a positive reaction is obtained, the x-ray examination of the chest should be repeated. It is difficult to do more than make an attempt to interpret the symptoms that are presented and to suggest further clinical investigation.

POSSIBLE STERILITY IN PULP WORKERS

To the Editor—I should like information regarding sterility of a person working with sulfurous acid and chlorine used in the manufacture of pulp. I have a patient who has worked in the pulp mill four years and has one child 2½ years old. For the past two years he has worked in the concentrated atmosphere of sulfurous acid and chlorine and his wife has been unable to become pregnant. There are two other men working in the same department as pipe fitter and lead burner, one has worked five years, the other four years. Neither has any children. Others work around the same part of the plant at intervals but do not spend their entire time in this department and they do not seem to have any special trouble. Is the handling of these chemicals likely to produce sterility?

KENNETH D. GRAHAM, M.D., Aberdeen, Wash.

ANSWER—Sterility in the male is not apt to be associated with industrial exposures to sulfurous acid or chlorine. At least such exposures will probably not lead to sterility as a direct and characteristic result. This query states that exposure is to a "concentrated atmosphere" of sulfurous acid and chlorine. Sulfur dioxide and more especially chlorine are so irritable that it can be reasonably doubted that large quantities of either were inhaled by these workers. Among workers engaged in this occupation in other pulp mills there is no known evidence of sterility. Instead, these workers may present evidence of chronic bronchitis, persistent coughing, crooked teeth or gastrointestinal disturbances. As a result of general depletion it is conceivable that a worker may become sexually impotent, but the probability of any such occurrence should not be emphasized. Under these circumstances it may be well for the physician in charge to make appropriate tests on these workmen to establish the presence of viable spermatozoa in customary numbers for the normal male. Further, adequate examination of the wives in question may lead to the demonstration of adequate causes for infertility. If for any reason lead enters into the operations involved, such for example as an impurity in the sulfurous acid, sterility of the male is possible, but in this case there should be other and more readily demonstrable evidences of lead poisoning.

DIFFERENTIAL DIAGNOSIS OF HYPERINSULINISM

To the Editor—A man aged 40 normal in every respect except for attacks of weakness appearing irregularly and lasting from fifteen minutes to one hour has low blood pressure: 90 systolic and 60 diastolic, a basal metabolic rate of minus 11, blood sugar 90 mg. and blood calcium 12 mg. I believe that this is a case of hyperinsulinism or hypoglycemia. He has been on treatment of low sugar and high fat diet with injections of adrenal cortex extract with improvement. Can you offer any further suggestions as to diagnosis or treatment? Please omit name and address.

M D, Virginia

ANSWER—One is not certain whether the blood sugar determination of 90 mg. was made during such an attack as described or whether it was from a routine sample taken in the morning after the usual overnight fast. The same doubt applies to the significance of the low arterial tension. If these observations have been made between the attacks of weakness they should be repeated at the time of such an episode, if this is at all possible. Typical attacks due to hypoglycemia are usually relieved promptly by the ingestion of sugar, orange juice, candy containing dextrose or Karo syrup taken promptly, should abort the sense of profound weakness. Arterial hypotension, on the other hand, may be considerably increased under certain conditions and thus cause symptoms. Fatigue is a common reason for the aggravation of chronic hypotension. The postural form of hypotension is being more and more clearly defined: vertigo, presyncope, extreme weakness and sometimes actual syncope occur when the patient changes from a recumbent to an erect position. These symptoms disappear when the head is lowered. Many of these patients learn to correct for the failure of the circulatory reflex by bending down as they

to tie their shoe laces when an attack appears. In postural hypotension it is more unusual for such an episode to last an hour.

Neurocirculatory asthenia (irritable heart), tuberculosis, organic cardiac disease with periods of fibrillation, petit mal epilepsy and marked and prolonged fatigue are other diagnostic possibilities. One is curious to know what preceded the onset of these attacks and whether they appeared abruptly or gradually. The description could apply to the common and distressing "postinfluenzal asthenia" in which arterial hypotension, moderate hypoglycemia, cold clammy sweats, vasomotor instability and severe apocamnosis are conspicuous manifestations. Adequate rest, small but more frequent meals, and strychnine sulfate 0.001 Gm (one-sixtieth grain) before meals are valuable therapeutic aids in this semuniversal sequel of influenza.

Further data are needed to make any more accurate diagnosis, and suggestions with regard to treatment must depend on a more explicit knowledge of the etiology of the syndrome.

THERAPY OF SYPHILIS

To the Editor—After an active course of treatment given properly and consisting of neoarsphenamine mercury preparations and close attention to the minutiae of treatment for two years when can one expect that the arsenic and mercury will leave the body? Does any of this arsenic and mercury circulate in the blood long after treatment? Has the presence of arsenic and mercury in the blood any effect on the Wassermann reaction? During the past year I have had occasion to have the Wassermann test performed on three patients. One had a negative reaction one year after completing treatment and now (several years later) has a 4 plus Wassermann reaction. Reinfection is not likely in this case. One patient has a Charcot joint and after active treatment for years now presents a 4 plus Wassermann reaction. One patient with a scaly eruption on the palms of the hands and the soles of the feet has a 4 plus Wassermann reaction after discontinuing treatment fifteen years ago (probably mercury inunction and potassium iodide and mercury iodide and so-called mixed treatment). Furthermore I had occasion to send a patient who had a fresh chancre to the city hospital for treatment and he reports to me occasionally. He tells me that some of the patients receiving treatment in the venereal clinic have been coming six and seven years and they are of the opinion that syphilis is never cured permanently. Probably the presence of those heavy metals (arsenic and mercury) in the blood stream if they get there interferes with the correct reading of the Wassermann test. If the arsenic and mercury really cure the disease the number of cases of dementia paralytica and takes should decrease. Is this so? New hospitals for the insane are being erected all over the country and they are probably all pretty well filled up. It seems to me that the old treatment of inunction and potassium iodide to the limit has done about the same as the newer treatment—makes symptoms disappear and that is all. I know that some patients get arsenic and mercury fast but how can one tell that except by using the Wassermann test and then this is just an alibi. I feel that the Wassermann test is ideal for diagnosis but not as an index of cure.

M D New York

ANSWER—It will be difficult to answer the various questions in detail. After an injection of neoarsphenamine a large proportion of it is excreted from the body within a week, and with an injection of trypanamide most of it is excreted within thirty-six hours. With injections of mercury compounds much will depend on the type of remedy employed. With a soluble injection most of it will be excreted within a period of one or two days, while with a preparation such as mercuric salicylate most of it will be excreted within a week. These are the mercury compounds most frequently employed at present. Arsenic and mercury in the blood would not have any effect on the Wassermann reaction.

The first patient probably has a relapse type of Wassermann reaction at least and perhaps a relapse syphilis. The patient should be looked over carefully, especially from the standpoint of cardiovascular syphilis and of central nervous system syphilis. He should have a lumbar puncture. This examination will probably reveal the reason for his four plus Wassermann reaction.

It is not unusual for a patient with Charcot's joints to have a persistent Wassermann reaction despite active treatment. After all what is being treated is the patient's syphilis and not his Wassermann reaction.

It is difficult to determine the nature of the third patient's scaly eruption on the palms and soles. It may be that he has a scaly syphiloderm. On the other hand, it may have nothing to do with his syphilis. The same remarks apply here as to the second patient.

The correspondent should read the various articles that have been coming out in the past few years in *Venereal Disease Information* and in *THE JOURNAL* from the Cooperative Clinical Group, various phases of syphilis are handled in these papers. Also the recent outline of the treatment of syphilis by H. N. Cole (*The Use of Antisyphilitic Remedies* *THE JOURNAL*, Dec 26, 1936, p 2123). The Cooperative Clinical Group has found

that the results of continuous therapy, using alternating courses of an arsenical and of a bismuth salt in series of from ten to twelve injections, for a total of three series of each, in an early case of syphilis, give a high percentage of cures. A cure is not necessarily considered in terms of Wassermann reactions but rather in the amount of treatment the patient has had and his freedom from evidence of syphilis thereafter.

REMOVAL OF FLOWERS FROM SICKROOMS AT NIGHT

To the Editor—Plants and flowers in rooms occupied by the sick are generally removed from the rooms at night. Years ago many people believed that night air of itself was detrimental to health and in consequence closed their windows at night. With this shut in condition at night observers of old were probably correct in concluding that certain specific plants or flowers left in such rooms at night gave off particles odoriferous or otherwise that in some way caused more or less mental or physical distress to the occupants of those window-closed rooms. How ever today where rooms occupied at night are as well ventilated as those occupied during the day it seems doubtful to me—ventilation being the same—whether there is any good reason why plants or flowers must be removed from a room at night when so far as can be determined they cause no discomfort during the daytime. It is so easy to be mistaken that I shall be pleased if you will advise me regarding the general opinion on this subject.

G W TYRRELL MD Perth Amboy N J

ANSWER—There are no sound medical reasons why flowers should be removed at night from sickrooms. Conceivably a patient might be sensitized or irritated by flowers in a sickroom, but not more so at night than during the day. Reasons other than medical may be more significant, even though falling into the category of the whimsical. Both the patient and the flowers need to get away from each other to be appreciated. The return of flowers in the morning becomes an event, a break in monotony, a welcome visitor. Few patients would choose to have their human visitors remain indefinitely. Besides getting away from the patient overnight, the flowers may be refreshed by the lower temperatures out of the sickroom.

SENSITIVITY TO HEAVY METALS IN SYPHILITIC PATIENT

To the Editor—A man aged 53 under treatment for latent syphilis has had a course of bismuth salicylate in oil 1 cc intramuscularly each week for twelve weeks. This was followed with neoarsphenamine 0.6 Gm intravenously weekly for twelve weeks. The second course of bismuth was then started (the same bottle of bismuth salicylate). After the second injection there was a generalized punctate pruritic eruption most severe on the extensor surfaces. For the third injection I used mercuric cyanide one-sixth grain (0.01 Gm). After a few days the rash disappeared. He was given two more injections of the mercury when a red papular pruritic eruption appeared generalized but most pronounced on the extensor surfaces. Following this he was given a rest period of three weeks (by his demand). The rash disappeared as before in a few days. Two weeks after the last injection there was a left sided orchitis which subsided in about a week. He was then (three weeks after the last injection) given 1 cc of bismuth salicylate again. The second injection was followed by a rash similar to the first type of rash. Since he refused further hip treatment and since it was over twelve weeks since the last course of arsenic he is now back on arsenic. Repeated urine examinations reveal an occasional trace of sugar both during and after the eruptions. Physical examination is essentially negative. Is it possible that he is sensitive to both bismuth and mercury? What preparation should be used when the present course of arsenic is completed?

M D Michigan

ANSWER—Cutaneous reactions to bismuth are uncommon but are seen frequently enough to make the inference justifiable that this patient is sensitive to the heavy metals. It is not an uncommon occurrence, however to find that some of these patients are sensitive to the local anesthetic which is incorporated in some of the bismuth preparations by the manufacturers. It might be well to make certain of this point by doing a patch test to the solution used and particularly to the anesthetic if any is present in the preparation. Frequently patients who are sensitive to one or two of the metals used in the treatment of syphilis are sensitive to all of them. As this patient is 53 years old and a diagnosis of latent syphilis has been made implying that the spinal fluid and cardiovascular examinations are negative, the fact that will determine the need for continued treatment is the duration of the syphilis. If the infection has been present twenty-five years or more and the patient has only a positive Wassermann reaction to show for it, there is no need of jeopardizing him by continued treatment to the point of developing a blood dyscrasia or an exfoliative dermatitis. If the infection is a comparatively recent one (two or three years in duration) it would be well to discontinue all treatment for six months and then start with small amounts (one-fourth the usual dose) of bismuth noting the reaction. If he again reacts to the mercury and bismuth it would seem advisable to discontinue further treatment.

POSSIBLE LATE EFFECTS OF SPIDER BITES

To the Editor—A married man aged 45 a barber states that about three years ago while on a fishing trip he was bitten on the leg by a spider of unknown variety. There was moderate pain and swelling for perhaps half a day with rather prompt subsidence of symptoms. Since then he has been bothered greatly at more or less frequent intervals by the occurrence of itching and burning wheals and nodules on all his extremities which come on toward the close of day and last most of the night. He insists that he never had the condition before the spider bite and is sure it is a direct result. Please inform me whether it is possible for a spider bite to sensitize a patient and if there is any treatment likely to overcome the condition.

M D North Carolina

ANSWER—Residual symptoms in the form of tingling and burning, or transient spasms in the muscles of the extremities, have been reported to have persisted many months following the bite of the black widow spider, *Latrodectus mactans*. These are relieved by the administration of bromides or other simple sedative therapy. The condition described by the correspondent has not been previously recorded as a result of spider bite poisoning. The patient should be carefully examined for dermatographia, eosinophilia or other signs of allergy, as well, of course, as for local parasites such as scabies or pediculi, and other possible factors that may have complicated the picture.

TREATMENT OF CHRONIC PROSTATITIS AND EPIDIDYMITIS

To the Editor—In November 1935 a man consulted me concerning a urethral discharge of about three days duration. He gave a history of having had gonorrhea some ten years before with a complete cure or so he was told by his physician. In the present illness there was little burning or pain and the discharge was only moderate thin and white. Numerous slides were negative for gonococci. I made a diagnosis of nongonorrheal urethritis and proceeded with the usual treatment. The prostate at this time was tender slightly boggy and moderately enlarged. In December while the patient was out of town for two weeks he suffered with right sided epididymitis and was kept in bed for the most of this time. When he returned this trouble was in the decline but I avoided active treatment of the urethritis for some time. When I felt it safe to do so I proceeded with the treatment at various times using neosilvol mercarbolid ptoass permanganate irrigations neoarsphenamine and zinc sulfate. Besides these I used silver nitrate once or twice sounds and prostatic massage. By June 1936 nearly all symptoms had disappeared but the patient would have a watery discharge every third morning. This would persist for half a day. At this point I referred him to a genito-urinary specialist for examination. Urethroscopic examination revealed two small cysts near the bladder neck which were fulgurated but there was no pus or evidence of infection anywhere in the urethra prostate or seminal vesicles. A check up two months later by the same man showed no change except that the cysts were gone and the urethra was slightly inflamed. Since this the patient has continued to have the slight discharge every third or fourth day and the urethra continues to feel irritated. He has refrained from intercourse and alcohol for long periods without relief. I will appreciate it if you can give me some suggestions of the possible diagnosis and treatment. If I am able to isolate *Trichomonas* what is the treatment in the male? What would you suggest to allay the irritation in the absence of infection or foci of infection? What is the danger if the condition is not checked? I neglected to mention that there is no stricture although the patient had one several years ago. Please omit name and address.

M D Wyoming

ANSWER—The patient had and possibly still has a persistent infection in either the prostate gland or the seminal vesicles or both. One must bear this in mind because of the fact that the prostate on examination was tender, slightly boggy and moderately enlarged, although nothing was said about the prostatic fluid at the time the patient was first seen.

Evidence is presented here that the patient had infection in the seminal vesicles because he developed a right sided epididymitis. The fact that urethroscopy disclosed a few cysts at the bladder neck is suggestive that he had infection in the prostate at that time. Chronic infection in the prostate and vesicles is a common cause for the persistence of a slight urethral discharge and often is a factor in the production of urethral irritation.

The use of heat by rectum is important in the treatment of this group of patients. The heat may be applied to the prostate through the rectum by means of a psychrophore using hot water, an electrical heater, hot rectal irrigations or sitz baths. Many patients object to the use of sitz baths at the time of year mentioned because they believe that sitz baths predispose them to colds. The most convenient way of using heat is by means of an electrical prostatic heater or one might use hot rectal irrigations, but this often upsets the bowel.

Next in importance is careful systematic, regular massage of the prostate and vesicles. This should be carried out on a full bladder. The patient should be instructed to bend over a chair or an examining table so that the prostatic fluid can be obtained at the external urethral orifice. This fluid should be

examined under the microscope for the presence of pus. It might be well to stain the fluid for the presence of organisms. The prostatic heat and massage should be continued until the strippings are free from pus when examined under the microscope.

In this instance there seem to be no reasons why the patient should refrain from sexual intercourse, nor is it necessary to refrain from alcohol.

The correspondent says that the patient has no stricture, although he had one years ago, therefore if repeated microscopic examinations of the prostatic strippings are free from pus, a few sounds should be passed. Local treatment to the urethra is hardly necessary other than the use of a hand injection morning and evening. This injection should contain a mixture of zinc sulfate and alum and phenol (carbolic acid), 0.25 Gm (4 grains) each dissolved in 120 cc (4 ounces) of water. The patient should hold the fluid in the urethra for about thirty seconds.

VITAL RATES IN CANCER AND DIABETES

To the Editor—I am preparing a chart on the vital rates to cancer. Would you please furnish me with (1) the 1936 death rate for cancer (2) the incidence rate for cancer for each year since 1900 (3) the age incidence for cancer deaths and (4) the number of five year cancer cures reported for each year since 1900. Also may I ask your opinion as to why the death rates in cancer are going up? I realize that you may not have the answers to these questions prepared for many years yet I will appreciate your giving me what information is available. What is your opinion as to the increase in the death rates for diabetes mellitus?

EDWARD D MAIRE M D Grosse Pointe Park Mich

ANSWER—1. The death rate from cancer for 1936 is not yet available for the general population of the United States. The standardized death rate from cancer among the industrial policy holders of the Metropolitan Life Insurance Company was 86.2 per hundred thousand as contrasted with a rate of 86.7 in 1935 and 88.2 in 1934. The trend of the death rate among these millions of insured lives is a fair indication of what is occurring in the general population of the United States.

2. Data are not available on the incidence rate of cancer in the United States. Probably a half million persons are afflicted with one form or another of cancer at the present time.

3. The death rate from cancer increases progressively with advancing age, as shown in the accompanying table.

Averages of Annual Death Rates from All Forms of Cancer per Hundred Thousand by Sex and Age, Ages 1 to 74 Years

Age Period Years	Metropolitan Life Insurance Company		Industrial Department		1911 1935
			White Males	White Females	
1 to 74*			75.4	89.6	
1 to 24*			3.1	2.8	
25 to 44*			23.5	51.7	
45 to 74*			352.9	385.1	
1 to 4			3.7	3.6	
5 to 9			2.0	1.7	
10 to 14			1.8	1.8	
15 to 19			3.5	2.8	
20 to 24			4.8	4.5	
25 to 34			9.8	20.9	
35 to 44			41.4	92.1	
45 to 54			157.4	231.3	
55 to 64			416.0	428.0	
65 to 74			765.7	722.4	

* Standardized for age

4. In 1934 there were 2,077 cases of five year cures reported at the Clinical Congress of the American College of Surgeons.

The increase in the crude cancer death rates over the past quarter of a century may be attributed largely to the aging of the population and to the increasing frequency with which cases of the disease are being recognized.

The recorded increase in the death rate from diabetes mellitus over the past twenty-five years has been due to

- The growth of that portion of our population which is particularly susceptible to the disease—older persons city dwellers, and certain foreign race stocks.
- Changes in the social environment that favor the development of the disease—the growing use of machines and higher standards of living.
- The more frequent diagnosis of the disease.

It is to be noted, however, that the diabetes death rate among Metropolitan industrial policyholders has remained stationary for the past five years.

DIAGNOSIS OF MENTAL DISTURBANCE

To the Editor—I am just wondering if you and your staff would be kind enough to give me some information regarding a woman, aged 22 who I think is insane. She is a habitual masturbator has been interested in various religious cults that believe in and teach mental science has gone to college three years and has studied art. She has intervals of intelligence with lapses into vicious murderous tendencies. She has been treated by many of the doctors in Los Angeles ranging from gynecologist genitourinologist and hormonologists to psychiatrists. The onset was sudden when she was taking the mental religious study and at the same time attending cocktail parties. She has been under the care of nurses ten months and has had all the laboratory tests made that are known as far as I know but I do not know the dependability of the various tests. M D California

ANSWER—The patient under consideration seems to have maniacal attacks, the nature of which cannot be determined by the information submitted in the question. Maniacal attacks may be the symptom of an unrecoverable psychosis or a temporary phase of a more benign condition. It is only by careful psychiatric study that the differentiation may be possible and adequate treatment prescribed.

BLACK WIDOW SPIDER BITE

To the Editor—I desire information concerning the late effects of a black widow spider bite. A robust man aged 35, suffered such a bite about six months ago. Within a short time he experienced severe abdominal pain nausea and vomiting and muscular cramps in both arms and legs. He improved under appropriate treatment and was released as well by his physician. The period of treatment lasted about four weeks. However, there has persisted in a mild form cramping pain in the arms and legs as well as abdominal cramps and muscular weakness to such an extent that he is unable to do any work. Is there anything known about the late effects of black widow spider bite? Please omit name. M D, Oklahoma

ANSWER—Paresthesias, numbness, tingling and transient muscle spasms, as well as general weakness, have been noted to persist in some instances of arachnidism for many weeks or months. These residuals are generally most marked in the muscles of the calf, but they may affect the entire lower extremities and occasionally the arms and the abdomen. Their occurrence does not appear to be dependent on the severity of the initial symptoms or on the age of the patient. The eventual prognosis is good, as the severity of these sequelae generally gradually diminishes. Massage and stimulation of the circulation of the affected muscles, mild sedation and reassurance of the patient regarding ultimate recovery may accelerate convalescence.

RABIES VIRUS IN EPILEPSY

To the Editor—Have you any report on the efficacy of antirabic virus as a treatment for epilepsy? A patient brought to my office a clipping from a Chicago paper under the name of Dr. Herman A. Bundesen which stated that beneficial results had been obtained in several cases of epilepsy that have been treated with antirabic virus. M D Nebraska

ANSWER—This question is best answered by giving the pertinent facts in the treatment of fourteen patients with recalcitrant epilepsy by means of antirabic vaccine. None of the patients were taking any medication during the active vaccine treatment. Injections were given daily for twenty-one days. The seizures of eleven patients recurred during and after the treatments. Two patients had no recurrences of any seizures until two months following the conclusion of the injections. The third patient had no seizure during the treatment, but two weeks after the last injection the seizures recurred and finally the patient went into status epilepticus and died. It is thus obvious that no beneficial results have been obtained from antirabic inoculations. Such treatment is therefore not recommended for the convulsive state (epilepsy).

USE OF TETANUS TOXOID

To the Editor—I just read an article about tetanus toxoid alum precipitated. Can you tell me whether the prophylactic action of the toxoid has been proved? JUDAH MINKIN M D Bronx New York

ANSWER—Tetanus toxoid seems to be gaining in recognition as an effective, harmless preventive of tetanus. Investigation has shown that in animals and in man tetanus antitoxin is produced in response to immunization with toxoid. In France such immunization has markedly reduced tetanus in army horses, and centers have been established for immunization of workers exposed to tetanus infection. The introduction of immunization in the army is under consideration. According to Ramon (*Rev d'immunol* 1: 37 [Jan.] 1935) the best results are obtained by the usual three injections of the toxoid alum precipitated followed by a further injection a month or more after the third injection or on the occasion of dangerous trauma.

The immunity is believed to endure for several years. The Council on Pharmacy and Chemistry has accepted Tetanus Toxoid Alum Precipitated for N N R and describes the brands of the National Drug Company and the Lederle Laboratories.

DIET FOR PANCREATIC FISTULAS

To the Editor—What particular diet has been used in helping to close pancreatic fistulas? I believe that diet alone has helped close pancreatic fistulas following marsupialization of a cyst and I should like to know whether this dietary treatment could be used to check the drainage following operation for acute hemorrhagic pancreatitis.

BERNARD J. FINEBERG M D Jersey City, N J

ANSWER—The diet referred to is that described by Wohlgemuth (*Berl klin Wchschr* 44: 47, 1907). It is based on the experimental work of Pavlov and of Boldyreff and consists essentially of an antidiabetic diet containing a low carbohydrate, a moderate protein and a relatively high fat content. More recently the addition of sodium bicarbonate has been advised.

The diet has been used with moderate, but by no means universal, success in the closure of pancreatic fistulas. Its use in the case cited should be worth trial but will probably be about as uncertain as its use in the condition for which it was originally described.

SCLEROSING FLUIDS IN BURSTITIS

To the Editor—Have any of the sclerosing fluids been used much in bursitis particularly prepatellar bursitis? If they have what fluids and what is the usual technic? C T UPCHURCH M D Melcroft Pa

ANSWER—Solution of quinine hydrochloride and ethyl carbamate and solution of sodium morrhuate in 5 per cent concentrations have been used to obliterate bursal cavities. The success of such obliterating injections will depend (1) on the possibility of removing the fluid from the bursal sac and (2) on the absence of severe inflammatory changes in the bursa. In the latter case an acute bursitis may be precipitated. A trial of the sclerosing method is permissible in the "cold" stage but, should a few injections given one week apart be unsuccessful, surgical excision is the most satisfactory treatment.

INTRAVAGINAL SANITARY PADS

To the Editor—Do the intravaginal sanitary pads cause a cervicitis? I have had two cases that cleared up when the pads were discontinued and hot saline douches instituted and recurred when they were again used. M D New Jersey

ANSWER—Ordinarily, intravaginal sanitary tampons do not produce any disturbance in the cervix. Conceivably however if these tampons are used by women who flow profusely a great deal of blood may be dammed back and retained in the upper portion of the vagina. This blood may perhaps irritate the cervix. There are numerous bacteria in the vagina and, since blood is an excellent medium for the growth of many of these organisms, stagnant blood may lead to some disturbances.

VESICLES ON PENIS

To the Editor—I have a young man aged 23 under treatment. He has a vesicular type of lesion on the penis. The lesions appear in crops of three or four vesicles over the corona and prepuce break down into small ulcers and disappear only to recur again. The Frei test for granuloma inguinale is negative. The Wassermann reaction is also negative. I have had this condition diagnosed as herpes prostaticus. Treatment to date has consisted chiefly of hygienic care of the parts washing with a solution of potassium permanganate. He has also had a few injections of antimony and potassium tartrate on the basis of granuloma but this has been of no avail. Could you advise any further treatment? Please omit name. M D Pennsylvania

ANSWER—If these lesions appear on the corona and prepuce, circumcision in all probability would prevent further recurrence. If this is not carried out, keeping the parts clean with a boric acid bath for the penis once or twice a day, followed by a dusting powder, may prevent recurrence.

SKIN SHRINKAGE IN PITUITARY OBESITY

To the Editor—A patient with pituitary dysfunction is being reduced on a high protein low carbohydrate diet and pituitary extract. The patient weighs 250 pounds (113 kg.). What can I do to shrink the skin and prevent flabbiness? The basal metabolic rate is plus 4.

M D New Jersey

ANSWER—How readily and how completely the skin in obesity will shrink to conform to the reduced size of the body depends on the elasticity of the skin and thus in turn on the age of the patient. Little trouble is encountered in patients under 40 years of age. Probably some benefit can be obtained by persistent massage.

Book Notices

The Treatment of Diabetes Mellitus By Elliot P. Joslin M.D. M.A. Medical Director George T. Baker Clinic New England Deaconess Hospital Boston With the cooperation of Howard F. Root M.D. Physician New England Deaconess Hospital Priscilla White M.D. Physician New England Deaconess Hospital and Alexander Marble M.D. Physician New England Deaconess Hospital Sixth edition Cloth Price \$7 Pp 707 with 22 illustrations Philadelphia Lea & Febiger 1937

This book has been conspicuous on the diabetic horizon for the last twenty years. It was conceived during the preinsulin epoch, was developed during the insulin epoch, and now thrives in a period which the author has named the Hagedorn era. Indeed, its revision so soon after publication of the fifth edition was necessitated by the discovery of protamine insulin by the distinguished Hagedorn and his associates of Copenhagen, whose report was published in *THE JOURNAL*, Jan 18, 1936. The Hagedorn era has already been shown to be an improvement for the diabetic patient. Protamine insulin, Joslin says, is the most notable advance in the treatment of diabetes since the discovery of insulin in 1921. The action of regular insulin was dramatic in lowering the blood sugar, but its effect was temporary and most cases required two, three or even four injections a day. With protamine insulin the injections may be reduced to one a day. The discovery of protamine insulin is responsible for the addition of two new chapters in this book and for much revision of the text. Protamine insulin is not perfect, and even more effective insulin compounds probably will follow in its train. It may be even hazardous to transfer a patient who has done especially well with regular insulin for years to protamine insulin, and it requires skill and patience on the part of the doctor and the patient. In long standing cases of severe diabetes the physician should insist on a period of three days' observation with regular insulin before starting protamine insulin. Dr. Joslin and his associates have treated more than 1,200 patients with protamine insulin, which he believes is the insulin for the general practitioner to use with the majority of his diabetic patients. Regular insulin, however, must always be available to supplement it in coma, infections and emergencies. Other excellent features of this monograph were mentioned in the review of the fifth edition in *THE JOURNAL*, April 11, 1936. Perhaps nowhere can one find in English more authoritative information about diabetes. The census reported 28,000 persons as having died from this disease in the United States in 1934. Diabetes has advanced in importance as a cause of death in the United States from twenty-seventh place in 1900 to ninth place in 1934, the diabetic death rate in the registration area of continental United States trebled in the twenty years 1880 to 1900 and doubled in the thirty years 1900 to 1930. A useful feature is chapter twenty-nine, on foods and their composition, in which are tabulated the composition of many foods with respect to the percentage of protein, fat and carbohydrate in them and the number of calories which they yield per hundred grams. There are chapters, of course, on the treatment of diabetes, on diets, on heart disease and diabetes, on pregnancy and diabetes, on diabetic coma, and on complications of diabetes in childhood.

The Glasgow Royal Maternity and Women's Hospital Medical Report for the Year 1935 Prepared by Malcolm D. Black M.B. Ch.B. F.R.C.P.S.G. Registrar to the Hospital Paper Pp 166 Glasgow Aldred & Coghlin Ltd 1936

A medical report of work done in an institution is almost impossible material for adequate review, one is so likely to fall into a critical attitude. This would be wholly unfair, since statistics must be thoroughly sifted and evaluated before comment is ventured on them. The hospital has 175 beds seventy-eight for antepartum cases, seventy-eight for lying-in cases and nineteen for "suspect" cases in an isolation block. Septic cases by arrangement, are transferred to the city fever hospitals. During the year, 4,477 patients were treated in the hospital, 423 per cent of whom had had some antepartum care, while the remainder had antepartum care elsewhere or were admitted as emergencies. Of the patients 3,067 were considered abnormal which was 68.5 per cent of all admissions. This high incidence of pathologic cases is contributed to by the

prevalence of rickets in the population served and by many other factors. In the hospital 3,306 babies were born, 2,863 of these were born alive while 443 (13.4 per cent) were stillborn. Eighty-one maternal deaths occurred in the hospital, giving a gross maternal death rate of 1.8 per cent. This gives an idea of the great number of abnormal cases (68.5 per cent) and of the severity of the complications encountered. A district service also is conducted by the hospital staff and 4,835 women were attended at childbirth in their own homes, 4,656 babies were born, 23 per cent of them stillborn. Two maternal deaths occurred at home, a maternal death rate of 0.04 per cent. Eleven women, first attended at home, subsequently died in the hospital, but their deaths were included in the hospital death rate.

This report is well worth a close and searching study from the standpoint of the pathologic conditions encountered, their treatment and the end results. Thus of 146 spinal anesthesias there were two deaths, six patients died who had chloroform anesthesia, with two deaths definitely attributed to the anesthetic. One patient died as a result of evipan and paraldehyde anesthesia. It is interesting too to note that of 233 cesarean sections done, 173 were classic, with five deaths, while in sixty cases the lower segment operation was done, with one death. Induction of labor was accomplished by artificial rupture of the membranes in ninety-six cases with six deaths, while a medical induction in 120 cases yielded five deaths. The operation of manual removal of the placenta was accompanied by a maternal mortality of 10 per cent. Naturally these figures must be dissected before conclusions are drawn regarding the dangers of the procedures mentioned. Blood transfusion was made available to ninety-two patients, and only two of these died from hemorrhage. The numerous and lengthy tables are well arranged and show a tremendous amount of painstaking effort in their compilation. Summaries of all fatal cases are included. These are interesting and instructive. In seventy-four of the eighty-one deaths that occurred the cause of death was ascertained by necropsy. The maternal and fetal mortality rates are total, no corrections were made. The emergency nature of a large portion of the service is indicated by the fact that 33 1/3 per cent of the maternal deaths occurred in the first twenty-four hours of hospital stay. In many of the admissions there had been untimely intervention on the outside. Many were brought from great distances, e.g., the Western Isles. In those patients who were considered to have had some antepartum care the death rate was 0.74 per cent, while of those who had no antepartum or inadequate care the death rate was 2.59 per cent.

The reader will find an obstetric lesson on every page. The report could serve as a model for other hospitals to follow.

The Digestive Tract: A Radiological Study of Its Anatomy, Physiology and Pathology By Alfred E. Barclay O.B.E. M.A. M.D. Honorary Radiologist to the Nuffield Institute for Medical Research Oxford Second edition Cloth Price \$12 Pp 427 with 296 illustrations New York Macmillan Company Cambridge University Press 1936

This is one of the most important books on the subject. It consists of three main parts accompanied by seven appendices. The first division deals mainly with general technique, emphasizing the use of a routine technique and the importance of a complete examination; moreover, it points out the radiologic risks and their avoidance by careful screening; it proves the necessity of protection and a safe equipment as well as a proper technique of palpation of the abdomen during the fluoroscopy. Different techniques of the radiologic examinations are mentioned. The author concludes the first part with a series of precepts for examination which he divides into "do's" and "don'ts". The second part is devoted to the radiographic examination of the "normal" gastro-intestinal tract; it is divided into anatomy and physiology. Barclay concludes that there is no absolutely normal alimentary tract "it may approximate to the average but there is no fixed standard of normality". He enumerates many factors that may be responsible for these deviations, the most important being respiration and posture. Here the author describes in detail how these factors influence the gastro-intestinal tract. Remarkable is his conception of the radiologic studies, which should always be a record of living anatomy, we are consequently not dealing

with definite and fixed relationships, as in descriptive anatomy, but with extremely changing points. For the same reason of extraordinary elasticity, fixed shape and fixed position of the viscera can most likely be denied. Fascinating are the thorough studies on the movement of the food throughout the entire alimentary tract, especially the experimental studies on the physiology of deglutition as well as the kymographic and cinematographic methods in establishing the knowledge of the gastric and colonic movements. The pathologic conditions of the alimentary tract are discussed and well illustrated in the third division. The essential roentgenologic symptoms are emphasized and the difficulties that may arise in the differential diagnosis are mentioned. The numerous illustrations are adequately reproduced. The chapter concludes with a detailed study of the gallbladder, the different modern techniques of cholecystography are given and the difficulties of interpretation of the roentgenograms are considered. Seven appendices discuss x-ray equipment, the quantity of rays used in diagnosis, the international recommendation for x-ray and radium protection as given by the Congress of Radiology in Zurich in 1934, and the photographic method of estimating exposure to x-rays. Barclay's own abundant experience, combined with his knowledge of previous and recent literature, makes the book valuable to every physician. It is not only instructive but it stimulates interest in various problems.

The Use of the Developing Egg in Virus Research. By F. M. Burnet. Medical Research Council Special Report Series No. 220. Paper. Price 1s. Pp. 58 with 6 illustrations. London: His Majesty's Stationery Office, 1936.

This report, prepared by Dr. F. M. Burnet, was issued by the Medical Research Council on the recommendation of its bacteriologic committee. It deals with a method that has been found useful in the study of human and animal diseases due to infection with filter-passing viruses and other infectious agents, including rickettsia and bacteria (Goodpasture, E. W., and Anderson, Katherine. *The Problem of Infection as Presented by Bacterial Invasion of the Chorio-Allantoic Membrane of Chick Embryos*, *Am. J. Path.* 13: 149 [March] 1937).

Because no filtrable virus has as yet been cultivated in a dead medium, methods for studying them must offer viable susceptible cells or a living host. Woodruff and Goodpasture in 1931 and Goodpasture, Woodruff and Buddingh in 1932 successfully infected the chorio-allantoic membrane of chick embryos with the viruses of fowlpox, vaccinia and herpes simplex and demonstrated that this living tissue provides a sterile medium in which viruses can be cultivated in the absence of contaminants. They also pointed out that the embryonic cells may be quite susceptible to certain viruses to which the newly hatched chick or adult fowl is entirely insusceptible. It was demonstrated also that the lesions induced in the membranes were quite analogous to those found in other hosts, cellular inclusions and general tissue responses being easily demonstrable and characteristic. Since these reports appeared, the membranes of the developing egg have been infected with a number of viruses by several investigators. Burnet lists fifteen viruses that have been reported thus far as successfully used to infect the membrane. The technic consists in incubating fertile hen's eggs for varying periods, usually from ten to fourteen days, then cutting a window through the shell with a silicon carbide disk attached to the chuck of a flexible shaft and operated by a small motor. The shell flap is removed with aseptic precautions, the inoculation made on the exposed membrane, and the opening covered either with a cover slip placed on a ring of petrolatum and paraffin or by replacing the shell and coating it with sterile paraffin. Burnet has introduced the modification of withdrawing the air from the air sac, through a small hole in the shell, thus enlarging, by displacing the contents, the field of operation. He finds that virus activity may be successfully titrated by placing on the membrane varying concentrations and counting the scattered focal lesions. Some viruses multiply best at temperatures lower than the optimum for incubating eggs. Practical applications of the method have been indicated by the use of this technic by Goodpasture and Buddingh and others in the preparation of vaccine for antismallpox prophylaxis. Burnet reports the cultivation of the virus of

human influenza on the membrane. A loss of virulence of one strain of influenza virus, with retention of immunizing power, suggests that experiments along these lines may lead to use of vaccines thus prepared to confer human immunity by intranasal administration. The method is adaptable to the demonstration of antiviral effect of immune serum and has led in this way to possible practical advantage in the poultry industry by the recognition of an attenuated, though immunizing, strain of the virus of laryngotracheitis. It is indicated that the method may have a great future importance, as its use increases, both in research work and in practical applications to prevention and treatment.

Clinical Allergy Due to Foods, Inhalants, Contactants, Fungi, Bacteria and Other Causes. Manifestations, Diagnosis and Treatment. By Albert H. Rowe, M. S., M. D. Lecturer in Medicine in the University of California Medical School, San Francisco. Cloth. Price, \$8.50. Pp. 812. Philadelphia: Lea & Febiger, 1937.

This book covers the entire field of clinical allergy, although particular attention is given to food allergy. The author has done pioneer work in the latter field. His widely known "elimination diets" are given here in detail for adults and children of various ages. In the many pages given to "elimination diets" there is such a variety that a fully balanced diet can be selected without difficulty. Special sections of the book are given to discussions of the wheat-free diet, the milk-free diet and the egg-free diet. Among his own patients suspected of food allergy, the author depends on "elimination diets" modified by definite skin reactions and history of food dislikes and disagreements. He believes that satisfactory skin reactions to all foods productive of clinical allergy are absent in from 60 to 70 per cent of the cases and yet he believes that skin testing with a complete number of foods and condiments is important. The numerous allergens that are used for skin testing are tabulated. The relative efficiency of the scratch test and the intradermal test is discussed. The place that the leukopenic index will finally take in the diagnosis of food allergy is not yet definitely decided. A considerable percentage of negative leukopenic index tests may be found in a group of persons who are allergic to certain foods. The author believes that the problems of food allergy can be solved as rapidly with diet trial, aided if desired by diet diaries, as with leukopenic indexes. There has been a remarkable advance in the knowledge of dermatoses arising from allergy. In the author's experience, practically all cases of urticaria and angioneurotic edema have arisen from allergic causes. The frequency of allergy as a cause of migraine is becoming more generally appreciated. Allergy as a possible cause of idiopathic epilepsy needs more definite consideration. In fact, all people are prone to evidence allergic disturbances at some time, particularly in the presence of a marked family history of allergy. Every physician, therefore, is confronted with allergic problems. Throughout the book, methods of diagnosis and treatment are emphasized. Chapter four has to do with the treatment of food allergy by elimination diets and general measures, and chapter seven is on allergic dermatoses. There are chapters on nasal allergy, ocular allergy, ingestant allergy, pollen allergy, gastro-intestinal allergy, bronchial asthma, allergic migraine and neuralgia, urogenital allergy, and on individual food and drug allergies and their control. There is a botanic classification of foods showing the relation of the groups into which they fall. Special sections are given to wheat allergy, tapoca allergy, egg allergy, milk allergy, allergy to fruits, allergy to vegetables, allergy to ductless gland products, allergy to fish, allergy to spices and condiments, allergy to cottonseed and allergy to drugs. In the appendix there are eighty-three individually reported histories of allergic cases and how they were treated. There are samples of the form for keeping a food diary and another for recording skin reactions. There are numerous recipes in the appendix showing how to prepare foods, for example, rice bread, rye bread, corn pone, salad, candies, preserves and beverages, as well as cereal-free foods. Finally there is an extensive bibliography, which occupies about eighty pages. The interesting subject of allergy is in the developmental stage. There is possibly a tendency at present to embrace a wider field than can be justified by the available knowledge.

Disease in Childhood A Clinical Study The First Year Birth to One Month One Month to Six Months Six Months to One Year By Robert S Frew MD FRCP Physician to the Hospital for Sick Children London Cloth Price \$11 Pp 669 with 89 illustrations New York & London Macmillan and Co Limited 1936

This is a unique volume Dr Frew is convinced that the most important factor in determining the characters that disease assumes in childhood is the age of the child, that although the causes of disease are constant through life, as the anatomy of the individual is constantly changing during childhood, the clinical signs manifest themselves differently at different ages. This is particularly marked during the first year, the period discussed in this volume. Some diseases are confined solely to this period, others display changes even in this short interval, while others have not yet made their appearance. He believes that this method of studying disease in childhood will produce a great advance in our knowledge of children's ailments. The author states that the facts on which the study is based are drawn with few exceptions from cases under his own care. He has analyzed 8,823 consecutive cases seen in the outpatient department and used a large number of other cases seen in the outpatient department, in the wards and in private practice. He has also utilized the results in nearly a thousand necropsies on children performed by himself, besides using the postmortem records of the Hospital for Sick Children Great Ormond Street. Consequently the "personal equation" is unusually pronounced throughout the text and discussion.

The volume, although confined to the first year of life is further subdivided into the sections given in the title, which necessitates considerable repetition. There are many charts, diagrams and tables but comparatively few illustrations. At the end of each age division is a table showing the comparative frequency of the various conditions at this age period. The extensive index is so arranged that each condition discussed can be referred to according to the age period. The bibliography is scanty, as most of the material and observations are the result of the author's personal study.

Because this volume represents a novel method of writing about diseases and conditions of infancy, and because it contains largely a prominent English pediatrician's personal point of view, many of the theories and conclusions are open to considerable discussion and disagreement. For example, much emphasis is placed on the coined term "hyperphlebaemia," meaning an excessive quantity of blood forced into the intracorporeal venous system during birth, before it is ready to receive it. Many of the disturbances of the new-born period are attributed directly or indirectly to this condition, certainly a question.

The Nutritive Value of Indian Foods and the Planning of Satisfactory Diets Health Bulletin No 23 Boards Price 2 Annas 3d Pp 48 Coonoor Nutrition Research Laboratories 1937

This little bulletin should be of interest to those seeking information about the nutritive value of Indian foods and should be of value as a practical guide for nutrition workers in India. It includes a brief summary of the dietary standards of the League of Nations as adapted to the native population of India, and tables which present the average composition of more than 200 common foods grown chiefly in the Coimbatore district. The list also includes some European vegetables grown in Coonoor at an elevation of 6,000 feet. The data reported include moisture, protein, fat, ash, fiber, carbohydrate, calcium, phosphorus, iron, calories and vitamins A, B₁, B₂ and C. The figures for the vitamins were obtained by spectrographic analysis for carotene and by titration for vitamin C, animal assay for vitamin B₂, and reports in the literature for vitamin B₁. The calcium and phosphorus values for different kinds of milk apparently were obtained from Sherman's tables, although no mention is made of this. Some of the food values reported are so different from the values reported elsewhere that one wonders if they are in error. It is doubtful, for example, that oatmeal contains 325 international units of vitamin B₁ per hundred grams. Figures obtained elsewhere would lead one to expect about 65 or 70 units. The reported value for the vitamin A (carotene) content of whole wheat likewise appears to be somewhat high. The maximum carotene content of spinach

grown in India appears to be about one tenth of the values obtained in the United States. Vegetable foods vary considerably in composition, yet these differences are so great that they deserve to be investigated further. The director of the Nutrition Research Laboratories at Coonoor is Dr W R Aykroyd, a well known nutrition expert, so it is likely that additional studies will be made.

Examinations and Their Substitutes in the United States By I L Kandel MA PhD Professor of Education and Associate in the International Institute Teachers College Columbia University With a preface by Walter A Jessup President of The Foundation Bulletin Number Twenty Eight Paper Gratts Pp 183 New York The Carnegie Foundation for the Advancement of Teaching 1936

By grants from the Carnegie Corporation to and through the Carnegie Foundation for the Advancement of Teaching, and under the direction of Dr Paul Monroe international conferences on examinations were held in England in 1931 and 1935. One of the results was the conclusion that because of varying educational and social conditions the problem could be best studied by investigations in each country. Dr Kandel's report presents a summary of the inquiry in the United States.

The volume is divided into four chapters, the first of which outlines the problem and its social setting. The second chapter traces the background of the traditional examination, its development, its operation, its advantages and disadvantages, together with a critical analysis of grading. The third chapter outlines the scientific attack on examinations as to selection and distribution in education, purposes, experiments with new type tests, state wide and nation wide examinations, and various comprehensive studies of determinative methods. The fourth chapter integrates education, examinations and the individual, pointing to the social needs and requirements that should serve as a guide to educational efforts. An appendix gives an account of the international conferences.

Well organized, well written and well printed, this volume deals principally with secondary and collegiate education. The historical background of college and entrance examinations is well covered. The evidence with regard to types of examinations is adequately surveyed. New type tests are favored, but without complete condemnation of the traditional forms. The report is modern in tone and adapted to what are believed to be changing social conditions. It is of importance to teachers and administrators in professional schools because many of the problems of collegiate education are also those of the graduate schools. The interpretation of the principles common to the two is predicated largely on a difference in emphasis of various features and their differential weightings. Of considerable interest to those who deal with admission of students to schools of medicine is the value attached to the cumulative records of individuals throughout common and secondary schools, to which for professional school purposes a similar record of collegiate work might well be attached. The analysis and application of these records deserve serious consideration.

Many of the facts disclosed by the study can well be applied to the professional schools, but it might be well if a similar inquiry was directed toward graduate education, especially in medicine because of the availability of material. The volume is distributed by the foundation and is recommended to those in schools of medicine who take seriously their duties as examiners as well as their responsibilities as teachers.

Les hépatonéphrites Par Maurice Derot et Renée Dérot Picquet Préface du Dr Pasteur Valléry Radot Paper Price 25 francs Pp 100 Paris J B Baillière et fils 1936

The hepatorenal syndrome is a constellation of clinical manifestations caused by a toxic or infectious agent acting simultaneously on the liver and the kidney. The authors state that there is no single causative factor and that no uniform anatomic basis exists for this syndrome except coincidental involvement of the two organs. The individual signs and symptoms of this purely clinical concept are then discussed in some detail. The syndrome consists essentially of jaundice, enlargement of the liver, albuminuria and retention of uric acid in the blood. Various additional features may be present, such as hemorrhages, nervous phenomena and, less often, generalized edema or hemolytic changes. The syndrome, being due to any one of a large variety of causes, has a variable prognosis and treatment is directed to the cause as well as to the more important

presenting signs or symptoms. Although it is doubtful whether a conception of a disease entity can endure unless it is based on some common etiologic factor rather than on mere grouping of clinical manifestations, the lucid manner in which the authors' thesis is presented, as well as the subject matter, should prove of great interest to those who wish to familiarize themselves with points of view distinctly different from those current in our country.

Handbook of Orthopaedic Surgery By Alfred Rives Shands Jr. B.A. M.D. Associate Professor of Surgery in Charge of Orthopaedic Surgery Duke University School of Medicine Durham North Carolina. In collaboration with Richard Beverly Raney B.A. M.D. Instructor in Orthopaedic Surgery Duke University School of Medicine. Cloth Price \$5 Pp 593 with 169 illustrations. St. Louis C.V. Mosby Company 1937.

The teacher of orthopedic surgery has long felt the need of a textbook that would present the subject in a form which could be read and understood by the student whose background is incomplete and whose future plans probably do not include an attempt to specialize in orthopedic surgery. Shands has prepared such a book. The text is easy to read and the illustrations consist entirely of artist's drawings, most of which are diagrammatic enough to show at a single glance diagnostic methods and technique. The arrangement of the twenty-four chapters of the book makes it easy to divide the subjects into a logical sequence for class lectures. Emphasis has been correctly placed on pathogenesis and diagnosis, although in a few instances more is said about specialized types of treatment than would seem to be necessary. In a text designed primarily to teach students orthopedic principles details of surgical technique could well have been omitted. Nevertheless, this is the best textbook of orthopedic surgery now available and sells for a price that the average student can afford. It is wholeheartedly recommended for the medical student, the orthopedic nurse and the general practitioner.

An American Doctor's Odyssey By Victor Heiser M.D. Cloth Price \$3.50 Pp 544 New York W.W. Norton & Co. 1936.

To review a volume which has already sold almost 200,000 copies is what the writers of rubber type remarks would call a work of supererogation. In this volume Dr. Heiser has been able to dramatize successfully the great campaign against epidemics of infectious disease in which, as a representative of the International Health Board, he has been a leader for many years. With the fine sense of the dramatic, a delicate sense of humor and a simplicity and sincerity of expression which are unique among writers in the health field, he has been able to attract great numbers of readers. No doubt much of the attractiveness of the book lies in the fact that the first person is used throughout, so that we feel ourselves part of the remarkable adventures that are depicted and thereby journey vicariously with Dr. Heiser into the far places of this world. The geniality, the judgment and the philosophy of its author come to life in this volume, which will well repay the time that any reader may give to it.

Die bioelektrischen Erscheinungen der Hirnrindenefelder mit allgemeinen Ergebnissen zur Physiologie und Pathophysiologie des zentralnervösen Griseum Von A. E. Kornmüller Kaiser Wilhelm Institut für Hirnforschung Berlin Buch Boards Price 7.80 marks Pp 118 with 33 illustrations Leipzig Georg Thieme 1937.

This important and scholarly monograph deals with the fluctuating electrical currents that can be registered with suitable apparatus when terminals (either silver wires or porous boot-electrodes) are applied to the brains of animals under local anesthesia. Many of the illustrations are specimens of curves so obtained from monkeys and cats. Human encephalograms also are discussed, the Berger rhythm seen when electrodes are applied to the intact skin either occipitofrontally or bitemporally, is discussed on page 79. In particular the author studied the cytoarchitectonics of the cerebral cortex as related to the wave forms obtained from various regions. Thus area 17 of the occipital lobe gives action currents in response to visual stimuli, but if one shifts the electrode beyond the boundary of this cytologically homogeneous region into an adjacent but different region, say area 18 the currents change. The difficult question of cerebral localization is taken up in the final chapter. The bibliography includes recent American work.

Light Therapy By Frank Hammond Krusen M.D. Associate Professor of Physical Medicine The Mayo Foundation University of Minnesota. Second edition. Cloth Price \$3.50 Pp 238 with 42 illustrations New York Paul B. Hoeber, Inc., 1937.

In this edition every chapter has been enlarged, there are new illustrations and many new references appear, more than doubling the number of those in the first edition. There is an increase of nineteen pages in the chapter on the physiology of light and a total of fifty-two new pages. The volume covers the entire field of light therapy, including infra red radiation. It quotes freely many authoritative statements, among which are those of the Council on Physical Therapy of the American Medical Association. The broad and painstaking work of that body, of which the author himself is a member, has done much to place light therapy on a sound basis during the past few years. In view of this fact the introductory sentence of the author's conclusions, "light therapy is still in a chaotic stage, retained from the first edition, does not appear quite warranted any more. The typography of the book is also markedly improved. Krusen's monograph is a useful and safe volume which should be in the possession of all medical men interested in light therapy.

Die "atypische" Pneumonie Eine klinisch röntgenologische und differentialdiagnostische Studie zugleich ein Beitrag zur Frage der "Grippe" und des Frühinfiltrats Von Dr. med. Frank Kellner Facharzt für Lungenkrankheiten leitender Arzt der Tuberkulosefürsorgestelle Kassel Sonder Band VI Immunität Allergie und Infektionskrankheiten. Praktische Ergebnisse der wissenschaftlichen Forschung und klinischen Erfahrung Herausgegeben von Rudolf Degkwitz et al. Paper Price 2.70 marks Pp 52 with 5 illustrations Munich Verlag der Ärztlichen Rundschau Otto Gmelin 1936.

This little volume comes as part of an irregularly appearing monograph series on immunology, allergy and the infectious diseases. Under "atypical" pneumonia the author reviews German roentgenologic literature on the pulmonary shadows frequently mistaken for tuberculous infiltration. He observed seventy cases located in various parts of the lung fields, only twenty-three cases involved the apexes. In thirty-two cases with lesions the shadows disappeared in two months. The clinical course and radiology of these cases and their relation to grip and to tuberculosis is discussed. He erroneously accepts the finding of tubercle bacilli as a decisive criterion in excluding pneumonia. The newer American work on radiography of the chest and the bacteriology of pneumonias has been entirely overlooked. Readers of current American medical journals will find no new point of view.

An Introduction to Pharmacology and Therapeutics By J. A. Cannon M.A. M.D. D.Sc. Professor of Pharmacology and Director of the Nuffield Institute for Medical Research University of Oxford. Fifth edition revised to accord with the British Pharmacopoeia 1932 and the United States Pharmacopoeia 1936. Cloth Price \$1.75 Pp 240 New York & London Oxford University Press 1936.

This little book, which bears a quotation from Oliver Goldsmith on its fly leaf, "Were angels to write books they would never write folios," must be a godsend to a student who is reviewing this subject for examination. It achieves brevity by selection and arrangement rather than by compression. The author aims to give the student who is beginning the study of pharmacology a readable short account of the scope and matter of the subject without making it a mere catalogue of facts. The author says "I can hardly hope that its sphere of usefulness will compensate for the time I spent in its compilation." We sincerely hope that it will.

Le varici Dal Dott. Demetrio Giorgacopulo 1. Auto chirurgo ospedal Regina Elena di Trieste Paper Price 25 lire Pp 131 with 13 illustrations Bologna Licio Cappelli 1936.

This short monograph on the injection treatment of varicose veins is the first of its kind in the Italian language. This is all the more amazing, as Schiassi has been one of the pioneers of the injection treatment combined with multiple ligation. The author discusses the anatomy, physiology and pathology of varicose veins and describes the history, indications, technique of complications, results and failures of the method. He lists all the known sclerosing solutions with the exception of the oleate, but does not seem to profess any special choice. The volume does not contain any information that could not be obtained from the several monographs in the English language. The illustrations are poor and not original.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Life Insurance Misrepresentation that Voids a Policy, "Attended by a Physician" Construed—In her application to the defendant insurance company for a policy of life insurance, the insured represented that she had never had cancer, had not been attended by a physician, and had not had any treatment within the preceding five years at any dispensary, hospital or sanatorium. Within a little less than one year after the date of her application she died of a cancer of the uterus. The plaintiff, the beneficiary under the policy, sued the insurance company to recover the benefits stated in it. The company denied liability, charging that the insured in her application for insurance made false and fraudulent representations concerning her health and the attendance of physicians. From a judgment in favor of the beneficiary, the insurance company appealed to the St. Louis court of appeals, Missouri.

The application for insurance was in two parts: part A dated April 7, 1931, and part B, dated April 15, 1931. On the day following the execution of part A of the application, the applicant went to a hospital. On the same day she was examined by a physician, who made a provisional diagnosis of cancer of the uterus. Her condition, he said, might have been due to something other than cancer. He did not tell the applicant at any time that she was suffering from cancer, and when he first examined her, April 8, she appeared to be in very good health. He made another examination on May 1. The insured entered the hospital on May 4 and a diagnosis of cancer was confirmed on the following day.

It may not be said as a matter of law under the evidence in this case, said the court of appeals, that the representation of the insured that she was not suffering with cancer was fraudulently made. The evidence does not show that she knew, either before or after the making of her application, that she was suffering from cancer. On the contrary, the testimony shows that she was purposely kept in ignorance of it. Even if it may be said as a matter of law that she was suffering from cancer at the time of making her application, it cannot be said as a matter of law that she knew that that was the case. The court could not agree with the insurance company that a misrepresentation made in an application defeated recovery under it, even though the representation was innocently made. The rule in the state of Missouri, said the court, is that where material representations made in an application for a policy of life insurance are warranted to be true, or the policy is conditioned on the truth of the representations or provides that the falsity of the representations shall void the policy, then the representations, if in fact untrue, will void the insurance though the representations were innocently made. But where there is no such warranty or provision in the policy, a misrepresentation, in order to void the insurance, must have been fraudulently made.

The defendant insurance company contended that the representations of the insured that she had not been attended by a physician and had not had any treatment in a hospital within the preceding five years were necessarily fraudulent. The representations of the insured, however, that she had not had any treatment in a hospital within the five years preceding her application for insurance was not untrue, said the court, for the evidence shows that she received no treatment "until long after the making of the application and the issuance of the policy." Nor was the representation of the insured that she had not been attended by a physician necessarily untrue or fraudulent. Questions answered in an application for insurance prepared and submitted by the insurer are always strictly construed against the insurer. To have been "attended by a physician," within that term as used in an application, there must have been an attendance with reference to some disease or ailment of a serious character, affecting the person's sound bodily health, and not in relation to a mere temporary indisposition or an ailment trivial in its nature. If, therefore, the insured was not in fact suffering

from cancer, the representation that she had not been "attended by a physician" was not untrue within the meaning of the term as used in the application. But if she was in fact suffering from cancer, it does not necessarily follow that the representation was fraudulent, for, if she was suffering from cancer, she did not know it, the fact being purposely kept from her. We do not believe, said the court of appeals, that under such circumstances she may be convicted of fraud as a matter of law for assuming that her ailment was not of a serious character but was merely temporary or trivial in its nature.

It is true that the application in this case contains a clause to the effect that the statements in the application shall form the basis of a contract of insurance. Notwithstanding this fact, however, under the express provision of the policy itself, the statements, in the absence of fraud, must be deemed representations and not warranties. So treating them, they are ineffectual to void the policy unless fraudulently made.

Accordingly, the St. Louis court of appeals reversed and remanded the case with directions that a new judgment be entered in favor of the plaintiff conditional on his remitting the assessment for attorneys' fees—*Houston v Metropolitan Life Ins Co (Mo)*, 97 S W (2d) 856.

Autopsies Liability for Performance of Autopsy on Illegal Order of Justice of Peace—Love instituted proceedings under the Texas workmen's compensation act for compensation for an injury allegedly suffered in the course of his employment. During the pendency of the proceedings he died. A claim adjuster for the insurer of Love's employer procured from a justice of the peace an order for an autopsy on Love's body. An autopsy was then performed by the county health officer, assisted by another physician, each of whom was paid \$50 by the insurance company. They furnished the company a copy of the report of the autopsy, which it filed in the compensation proceedings and thus defeated the claim for compensation. Love was not married. His parents were dead. He had lived with his brothers and sisters, but they were not notified that an autopsy was to be performed. They therefore sued the insurance company for damages for having caused an autopsy to be performed on the body of their brother without their consent. The trial court directed a verdict in favor of the insurance company and the plaintiffs appealed to the court of civil appeals of Texas, Beaumont.

The defendant insurance company insisted that the directed verdict in its favor was proper inasmuch as the autopsy was performed by the county health officer on the order of the justice of the peace, who, the insurance company contended, was authorized by statute to order it. Article 968, Code Criminal Procedure, 1925, however, the court pointed out, provides, in effect, that a justice of the peace may hold an inquest when a person dies in prison or is killed or from any cause dies an unnatural death otherwise than under sentence of law and when the body of a human being is found and the circumstances of death are such as to lead to suspicion that he came to his death by unlawful means. Article 970, Code Criminal Procedure, authorizes a justice of the peace, when an inquest is held, to order if he deems it necessary, that the county health officer perform an autopsy to determine whether the death was occasioned by violence and, if so, its nature and character. It is obvious, said the court, that the statutes just cited apply only to securing evidence for the suppression and prosecution of crime. There is, however, not a hint that the autopsy in this case was sought or held for the purpose of detecting a crime, it was sought by the insurance company for the sole purpose of defeating a claim against it for civil damages. The statutes do not authorize an autopsy for any such purpose. The justice was without any authority to order the autopsy, and to perform one under the undisputed facts disclosed by the record was unlawful. The brothers and sisters of the deceased were under a duty to preserve his body and provide for its burial. For that purpose the law gave them the right to possession of the body. Any interference with that right by mutilating or otherwise disturbing the body, without their consent, was an actionable wrong. It was therefore error for the trial court to direct a verdict against them.

The insurance company next insisted that even if the autopsy was unlawfully performed, it was procured by their local claim adjuster, outside the scope of his employment and not by virtue of any authority from the company, either express or implied, and that therefore the company was not liable. It clearly appears, answered the court of civil appeals, that the claim agent in procuring the autopsy was acting as the fully authorized agent of the insurance company, within the scope of his employment and in the exercise of the discretion given him in the investigation of and approval or rejection of claims against his company. But if he was not, still the insurance company is liable, because after the autopsy had been done it approved the acts of its claim agent, paid the physicians for performing the autopsy, and accepted the benefits by receiving the report of the autopsy from the physicians and filing a copy with the industrial accident board, which resulted in the dismissal of Love's claim.

The court of civil appeals accordingly reversed the judgment of the trial court and remanded the case for a trial on its merits—*Love v Aetna Casualty and Surety Co (Texas)*, 99 S W (2d) 646

Malpractice Physician Not Liable for Results of Original Injury—In instructing a jury with respect to the amount of damages to be awarded a patient for the alleged malpractice of a physician in treating a dislocated shoulder, a trial court errs in failing to distinguish between injuries and sufferings resulting from the accident causing the dislocation of the shoulder and those resulting from the failure of the physician to exercise due care in the subsequent treatment. Instructions permitting the jury to consider as an element of damages all the injuries suffered by the patient and to award compensation for all loss and suffering endured by the patient, whether caused by the accident or by the physician's alleged negligence, are erroneous. If the patient is entitled to recover anything, he is entitled to recover compensation only for those injuries which proximately result from the physician's negligent treatment—*Payne v Stanton (N C)*, 188 S E 629

Workmen's Compensation Acts Trauma in Relation to Sarcoma of Spine—In 1926 O'Brien fractured several of his ribs. In September 1934, in the course of his employment with the Salt Lake City Federal Emergency Relief Administration, he fell and injured his left hip, sustaining an incomplete fracture of the left acetabulum. He seemed to be recovering from the injury until, about four months after the accident, he began to suffer pain in his back. Roentgenograms at this time indicated that he had sustained at some previous time a slight compression fracture of his seventh thoracic vertebra. The roentgenologist, while not certain, believed that the fracture was older than the fracture of his acetabulum. In March 1935 an exploratory operation disclosed a sarcoma of the spinal column. O'Brien died about one month later. After an autopsy, a pathologic diagnosis was made "Endothelioma (Ewing's tumor) of the bodies of the lumbar vertebra with metastasis of the regional lymph nodes and pleurae of both lungs. Marked edema of the spinal cord with suppuration." The claimant, O'Brien's widow, instituted proceedings under the workmen's compensation act for compensation in addition to that paid up until O'Brien's death. From an order of the industrial commission denying compensation, she appealed to the Supreme Court of Utah.

The Supreme Court could not agree with the claimant's contention that the order of the commission should be set aside because the medical testimony showed that the trauma probably had caused the tumor. The medical testimony showed that O'Brien's death had been caused by the tumor, but beyond that, as viewed most liberally in favor of the claimant, it indicated only that it was probable that the tumor had resulted from trauma. It is not for this court, said the Supreme Court, to reverse the finding of the commission on the theory that testimony showing probability is so conclusive as to require a finding that the tumor was caused by the accident. If there is evidence both in favor of and against a proposition, it is a matter of weighing evidence which is the prerogative of the commission and not of a court.

Accordingly, the Supreme Court concluded that the commission had not acted unreasonably, arbitrarily or capriciously in finding against the claimant, and so it affirmed the order of the commission denying compensation—*O'Brien v Industrial Commission et al (Utah)* 61 P (2d) 418

Workmen's Compensation Acts Chronic Arsenic Poisoning an Occupational Disease, Not an Accident—The claimant was employed by a canner during the canning seasons, from 1929 until November 1934. She peeled pears and apples, and in doing so her hands were frequently in water and became softened. In November 1934 she noticed an aching pain in her left hand and observed a reddish rash on three of the fingers of that hand. The condition became worse, necessitating surgical treatment, the nature of which does not appear in the record. It was known that a residue of an arsenic spray remained on many of the apples and pears peeled by the claimant. Each year she and many of her fellow employees suffered from a similar eruption. To her knowledge, she had never had a break in her skin or a cut of any kind. Eventually, she applied for compensation to the industrial accident commission of Oregon, but the commission denied her claim. Thereupon she appealed to the circuit court, Multnomah County, and from the judgment of that court affirming the commission's decision she finally appealed to the Supreme Court of Oregon.

The expert medical witnesses agreed that the claimant's condition was due to her employment and they referred to her condition as an "occupational disease" or an "occupational rash." There was medical testimony also to the effect that, in the absence of a visible cut or break in the skin, the poison on the fruit could enter the claimant's system through a minute break in the skin or penetrate the skin through the hair follicles. The Supreme Court held that the claimant had not sustained a personal injury by accident arising out of and in the course of her employment and caused by violent or external means, within the meaning of the workmen's compensation act. Nothing unusual, said the court, had happened in the canning of the fruit. The claimant and her co-workers intentionally handled the sprayed fruit and placed their hands in the water. They knew the nature of the spray on the fruit. The court concluded that the claimant was not entitled to compensation, because she had sustained only an "occupational disease," and an occupational disease is not compensable under the workmen's compensation act of Oregon.

Accordingly, the Supreme Court affirmed the judgment of the circuit court upholding the award of the commission denying compensation—*Ryan v State Industrial Accident Commission (Ore)*, 61 P (2d) 426

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Parenteral Liver Extract Therapy in Pneumonia—Wilson and Carey have treated thirty cases of pneumonia with parenteral liver extract. These included eight cases of streptococcal pneumonia and one of staphylococcal, in the remainder the pneumococcus was most frequently found to be the causative organism. Five of the thirty patients died. All had pneumonia with a leukopenia or falling leukocyte count, three had pneumonia occurring in the course of a streptococcal septicemia, and two of these were the only patients to receive serum. They were given polyvalent antistreptococcus serum intravenously. No antipneumococcus serum was used. A leukocyte count of more than 15,000 was present in only eight cases at the beginning of treatment, the rest were below 15,000. The rationale of the use of parenteral liver extract therapy is as follows: parenteral liver extract stimulates leukocytosis, in some pneumonias the blood picture is characterized by a relative leukopenia or a falling white blood count, these cases offer a more unfavorable prognosis, therefore, parenteral liver extract given in these cases should stimulate leukocytosis and as a secondary effect improve the clinical picture and progress. The concentrated liver extract was injected intramuscularly in varying amounts, depending on the severity of the infection and the leukopenia developing during the course of the disease. The injections were made deep into the muscles of the buttock and deltoid regions. The average amount was 6 cc a day. A majority of the patients were kept in oxygen tents as long as dyspnea and cyanosis were present. Expectorants, such as ammonium chloride, were given. Morphine and codeine were given for severe pleural pains. An effort was made to keep the fluid intake between 3,000 and 4,000 cc daily. Liquid and soft diet were given in small amounts frequently. Whisky was prescribed in small amounts for elderly persons. No purgatives were allowed. If constipation became marked saline enemas were given. There was an approximate increase in leukocyte count of 70 per cent and the range was from 6 to 239 per cent. After an injection of concentrated liver extract the leukocyte count gradually rises for seven hours and then gradually falls. All but six patients responded by an increase in leukocyte count. There was a daily drop in the white blood count until liver extract treatment was started. Several patients

showed a marked increase in urinary output the day after parenteral liver extract was given. Pain occurs at the site of the injection, but this is moderate and of short duration.

Sulfanilamide in Type 3 Pneumococcus Pneumonia—Heintzelman and his associates discuss nineteen cases of type 3 pneumonia, nine of which were treated with sulfanilamide and ten with no special form of treatment. These cases occurred from September to March inclusive and the majority were under observation during January. Treatment consisted of the oral administration of sulfanilamide, augmented in a few cases by intramuscular injections of prontosil. Owing to the late arrival in the hospital of some of the patients, the first administration of sulfanilamide was sometimes considerably delayed. There was a general similarity between the two groups, although predisposing factors, complications, age and the like were somewhat more favorable to the treated group. Seven of the nine patients recovered and two died. In the other group of ten patients two recovered and eight died. In a group of thirty-three cases in the Pittsburgh area, but not under the authors' direct observation, nine patients recovered and twenty-four died. The mortality rate for all patients not treated with sulfanilamide was 74 per cent, that for the treated patients 22 per cent. Despite the fact that the number of treated type 3 cases is small and that the treated group was somewhat favored by the factors of age incidence and by the absence of significant complicating features, the nature of the difference in relative mortality in the treated and untreated groups appears to justify continued use of sulfanilamide in the treatment of type 3 pneumonia until a sufficient number of cases have been accumulated to justify a final judgment as to the efficacy of this mode of therapy.

Effect of Splanchnic Nerve Resection on Hypertension—Page and Heuer performed splanchnic nerve resection with interruption of the thoracic sympathetic chain on nine patients. Six were cases of essential hypertension varying in severity from mild to severe and ages ranged from 25 to 48 years, one patient, aged 25, suffered from early malignant hypertension and two, aged 18 and 25, from severe malignant hypertension. Splanchnic nerve resection was well borne in all cases, and there have been no complications or fatalities. The patients have not been harmed by the operation. The reduction in arterial pressure which occurred following operation was marked but within six months it had returned to the preoperative level in all patients. Subjective improvement consisting of lessening in frequency and severity of headaches, ease of fatigue, nervousness, tenseness and irritability occurred in six of the patients with essential hypertension, but in three improvement lasted less than a year. Improvement in those with malignant hypertension was transient. In one case of essential hypertension and two cases of malignant hypertension papilledema disappeared but in the latter cases reappeared within several months. Reduction in intensity of the constriction in the retinal arterioles occurred in all the cases except one of malignant hypertension, demonstrating that arteriolar relaxation occurs in regions other than those denervated. In most of the cases, constriction has returned after several months.

Pitressin for Control and Relief of Distention—In summing up the status of the clinical use of pituitary preparations for distention Frazier finds that there is no unanimity

of opinion as to their value. No explanation has been offered for the marked variations in their effectiveness. This, of course, includes the period prior and subsequent to the isolation of the vasopressor fraction of the posterior lobe. Before its isolation, extracts from the whole lobe were used and there is adequate explanation for the lack of uniformity of effect of these preparations, in the proved antagonistic action of the two fractions. Since that time, however, only the pressor fraction has been employed. While British and German authors continue to report satisfactory results, American surgeons have not only ceased to use the substance except occasionally but condemn its use in cases in which the distention is associated with peritoneal infection. The reason for this is not obvious unless it implies that there is some essential difference between the commercial preparations here and abroad. In an effort to determine the value of pitressin in postoperative abdominal distention and its associated symptoms, the substance was administered to ninety-four patients. The amount given subcutaneously varied from 0.5 to 1 cc every four hours for as long as ninety-six hours. Only three patients suffered reactions following the injection of pitressin. These were characterized by intense pallor, headache, shallow respirations and a rapid thready pulse. All were transient, lasting from ten minutes to one hour, and the patients recovered spontaneously without the administration of any stimulants. Blood pressure readings were determined on the majority of these patients just before and shortly after one or more injections. There was no marked rise or fall in either systolic or diastolic pressure. Pitressin has proved a valuable agent in the prevention and relief of abdominal distention due to adynamic ileus resulting from operative trauma and peritoneal infection. Reactions are few, mild and transient and associated with no danger to the patient. Its use is recommended in combating this distressing postoperative symptom.

Blood Changes in Tuberculous Patients Following Vitamin C and Orange Juice.—Radford and her colleagues hoped to enhance the resistance of tuberculous patients by giving them a superabundance of vitamin C. They selected 111 tuberculous patients with far advanced and generally fibroid tuberculosis, under sanatorium care. These patients received no other therapy than routine rest. They were matched up in sets of three patients each which were as nearly comparable as possible, one was used as a control, one received 500 cc. of orange juice daily and the third received 250 mg of vitamin C in its pure crystalline form. This was given in a synthetically prepared orange juice. The control group received only the synthetic orange juice. The original group could not be kept intact throughout, hence the results actually reported are for a period of three months in eighty-five cases, six months in seventy-one and nine months in fifty-six. At the end of the first three months of the experiment, of the cases treated with crystalline vitamin C and those treated with orange juice a definitely greater percentage showed a favorable course as judged by red blood cell count, hemoglobin, lymphocytes, monocyte-lymphocyte ratio and neutrophil-lymphocyte ratio, than did the controls. Also the albumin-globulin ratio appeared more favorable in the treated groups. At the end of six months of daily treatment there was still a marked improvement in

the blood cells as well as in hemoglobin between the treated groups and the controls. After nine months the two treated groups still show better percentages than the controls in red cell counts, and they compare favorably in respect to sedimentation rates and blood fibrinogen at this time. The orange treated group still shows a greater percentage of improvement in the neutrophil-lymphocyte and monocyte-lymphocyte ratios than do the controls, and the vitamin-treated group persists in showing a definitely better percentage of improvement in hemoglobin. The other changes have become quite negative. The improvement in the hemoglobin and red cell figures indicates a possible hematonic effect that merits further investigation. The system adopted offers a means of conducting a clinical experiment in tuberculosis that eliminates the personal factor as much as possible and reduces the results to a virtually numerical basis.

- *Relation of Fungus Infection of Grain Crops to Vasomotor Disturbances in Man. J. E. Klein. Chicago—p. 1708.

Fungus Infection of Grain and Vasomotor Disturbances in Man.—Klein suggests that the ingestion of foods subject to fungus infection over a period of years may produce a chronic intoxication by the contained ergot alkaloids and amines, which may be the cause of certain vasomotor disturbances such as acrodynia, Buerger's disease, erythromelalgia, Raynaud's disease and acroparesthesia. It seems advisable that serious attention be given to the problem of reducing these fungus infections of the common cereals by modern chemical treatment of infected seed and by improved milling methods. Plant pathology is of considerable significance in relation to human health and should be systematically studied from this point of view. The author studied the effect of ergotamine tartrate on six white rats. A solution of 25 mg of ergotamine tartrate was injected subcutaneously twice a week for two months. The drug was also administered daily in the drinking water in the proportion of 0.001 Gm to 8 ounces (240 cc) of water. Early in the experiment there was noted a pronounced cyanosis of the tip of the tail in the six experimental rats. A dry gangrene of the tail developed in two rats after the first month. The experimental animals seemed quieter than the four controls. One, however, developed symptoms of excitation rat

about the cage made unusual noises and acted in a strange manner. After two months all the animals were chloroformed and examined post mortem. No noteworthy abnormalities were found on gross examination. On microscopic examination the arteries of the tails of the experimental rats were found to be markedly constricted, so that almost no lumen was apparent. No inflammatory changes were observed. The various theories proposed at present for the explanation of acrodynia do not seem to be satisfying or conclusive. In view of the conflicting theories on the etiology of acrodynia, the theory that it is due to grain fungus intoxication is brought up for consideration on the basis of clinical and experimental data.

The Fungous Flora of Apparently Normal Skins—Downing and his co-workers studied 300 scrapings from the skin of fifty male and fifty female patients whose skin appeared to be perfectly normal. The scrapings were taken from the skin from behind the ears, from the corners of the mouth and from between the third fourth and fifth toes. Twenty-two filamentous fungi two of which were pathogenic to man, were isolated from the 300 scrapings. Scrapings from the toes were most productive, yielding twelve fungi, while those from the corners of the mouth produced six and those from the ears only four. The age and race of the patients, the disease and the length of time the patients had been in the hospital had no apparent correlations with the fungi cultured from their skin. Of the fungi obtained, twenty are known only as saprophytes or plant parasites, there is no evidence indicating that their occurrence on the skin was due to anything more than a chance contamination. Two of the fungi, *Epidermophyton floccosum* and *Trichophyton mentagrophytes*, both obtained from toes, were morphologically identical with the two species commonly obtained from lesions of epidermophytosis of the toes. Of the sixteen yeastlike fungi identified, all were potentially saprophytic. The bacterial flora was studied in twenty consecutive cases. The bacterial observations were not remarkable except for the fact that *Staphylococcus aureus* and beta hemolytic streptococci were never recovered from the blood agar plates. From scrapings from the corners of the mouth *Staphylococcus albus* was present in all cultures and was usually predominant. *Streptococcus viridans* was present in nearly all cultures but was rarely predominant. Gram negative cocci were present in three cultures, gamma type streptococci and *Staphylococcus citreus* were each observed in one culture. *Staphylococcus albus* was present in all cultures from scrapings from behind the ears being usually observed in pure culture and being always predominant. *Staphylococcus citreus* was present in four cultures, and gram positive bacilli *Streptococcus viridans* and diphtheroids were each observed in one culture. From scrapings from the toes *Staphylococcus albus* was present in all cultures, being usually observed in pure culture and being always predominant. Gram-positive bacilli were present in four, *Staphylococcus citreus* in three *staphylococci* with gray colonies in two and *Streptococcus viridans* in one.

Reduction of Postencephalographic Symptoms—By combining a modified continuous flow apparatus with the technic of Davidoff and Dyke, Schwab and his associates were able to reduce appreciably the reactions in thirty consecutive post-encephalographic cases. The inhalation of 95 per cent oxygen for three hours was followed by a prompt removal of most of the subarachnoid air during the three hours the patient was in the machine. Of the three hour encephalograms all fourteen showed satisfactory reductions in the air. The air does not return, as shown by the encephalograms taken fifteen hours later. The disappearance of the subarachnoid air was complete in twelve of the fourteen cases and nearly so in two. The procedure resulted in no pulmonary complications. The reactions were reduced in most cases. In eight of the cases reactions were minimal and were unusually short for encephalography. If small amounts of air or oxygen are used—from 30 to 50 cc—in the encephalogram the benefits of the technic are of doubtful value. Lumbar punctures made after the use of the oxygen machine showed a less cellular reaction than when it was not used. The use of solution of posterior pituitary hastens the return of cerebrospinal fluid and reduces the headache. The authors failed to use it in four cases, and the encephalograms showed the same reduction of the air, but the clinical improvement was less noticeable.

Vascular Occlusion in Multiple Sclerosis—By the use of a refined technic, Putnam demonstrated the existence of thrombi in various stages in cases of "encephalomyelitis" and multiple sclerosis. The frequent occurrence of vascular engorgement and perivascular hemorrhages in acute lesions and of vascular obliteration in chronic lesions is confirmed. Previous studies, experimental and pathologic, have indicated that vascular changes such as those observed are adequate to cause the alterations in the parenchyma characteristic of the two diseases. Thrombi also are occasionally to be found in organs other than the nervous system in cases of multiple sclerosis. The primary abnormality is to be sought probably in the clotting mechanism of the blood.

Hypothyroidism Without Myxedema—White collected ninety cases in which the basal metabolism rate was below minus 10 up to minus 42.5 without myxedema. The patients, all female, ranged in age from 14 to 68 years. The most common reasons for their seeking medical care were because they "just felt bad," having marked fatigue, nervousness or general aches and pains. Some miscellaneous complaints included sleepiness, palpitation, dyspnea, choking sensation, stomach trouble, gain in weight, sterility, excessive menstruation and amenorrhea. The fatigue of which the patients complained was out of proportion to their activity. Physical examinations were essentially negative. Seventy-nine of the patients were treated with desiccated thyroid. Of these, sixty-four were considered improved in that the nervousness and excessive fatigue disappeared, seven showed improvement and in eight there was no improvement. Of these eight, one improved on thyroxine. One improved after the addition of thelin to the treatment. Two patients treated with desiccated thyroid and compound solution of iodine improved. One treated only with compound solution of iodine showed improvement. The history is the most important factor in making a diagnosis of hypothyroidism without myxedema. The lowered basal metabolic rate was the only positive sign in most cases that otherwise seemed to be quite normal to the usual physical examination. Regardless of whether the thyroid is primarily or secondarily at fault, thyroid medication is efficacious in relieving the symptoms in the majority. The symptoms in some patients returned when thyroid medication was stopped. Some have been able to discontinue thyroid, and it is possible that a rearrangement of the endocrine balance has taken place as a result of the temporary support given a weakened thyroid by the administration of thyroid by mouth. The author feels that it is of the greatest importance to the gynecologists to recognize a hypothyroid condition because it may be a large factor in various forms of functional disturbances of menstruation. It is of importance to the obstetrician at all times. It may be the cause of sterility, and often it is the cause of spontaneous abortion and stillbirths. In considering sterility one must not forget that the male also may be hypothyroid. It is important to recognize hypothyroidism during pregnancy as a factor in controlling the weight of the mother, and also since babies of hypothyroid mothers have a tendency to be larger than those of normal mothers. Children born of a hypothyroid mother may have hypothyroidism. Following birth of a child, a hypothyroid condition may be a most important factor in delaying the return of normal strength.

Ill Effects of Heat on Workmen—Talbott and his co-workers examined the fifty-nine workmen who were admitted to the hospital for study during a period of ten weeks. All the men were employed by one of the steel companies in Youngstown, Ohio, and presumably stopped work because of the ill effects of heat. The clinical entities associated with exposure to high temperatures are thought to be heat cramps, heat prostration and heat pyrexia. The heat cramps syndrome was divided into three degrees of severity, myalgia and abdominal cramps are differentially discussed. The age incidence of the various groups was similar. Three fifths of the men included in the study had been idle one or more days before the onset of symptoms. Therefore it appears that idleness, either voluntary or enforced, increases susceptibility to the ill effects of heat. The changes in the concentration of constituents of the body fluids in patients with heat cramps were characteristic of a depletion of body water and sodium chloride. The blood showed an increased concentration of hemoglobin and protein and a diminished concentration of sodium and chloride. The concentration of chloride in urine samples obtained on admission was diminished. During convalescence there was a gain in body weight and a restoration of the disordered equilibrium. The pathogenesis of heat prostration is thought to be peripheral circulatory collapse, and the pathogenesis of heat pyrexia a failure of the heat regulating mechanism. The treatment and prevention of heat cramps involve a replacement of the salt and water lost as sweat during working hours. It is possible that certain other disorders due to heat may be prevented by salting drinking water.

Fresh and Stored Typhoid Vaccines—In view of the difference of opinion, Mishulow and her co-workers again investigated the potency of vaccines after storage for a period of several years. They selected typhoid and paratyphoid A and B vaccines, since laboratory animals respond readily to immunization with them. The vaccines were prepared and tested individually for agglutinin stimulation in rabbits and for protection against virulent cultures in mice. These vaccines were tested when freshly prepared and at intervals after storage for from two and one-half to three years at 8 to 10°C. Rabbits were given three intravenous injections of typhoid vaccine with a total of one-half the human prophylactic dose. The rabbits were bled one week after the last injection of the vaccine and their serums were tested for agglutinins with the corresponding

antigen There was considerable variation in the individual response of the rabbits in each series tested, but at the end of two and one-half years of storage there was no demonstrable deterioration in the ability of the vaccine to stimulate agglutinins in rabbits There was no difference in the length of time the agglutinins persisted in rabbits that were immunized with the freshly prepared vaccines or after they were stored for one year Weekly rather than daily injections gave better agglutinin response Mice were given one intraperitoneal injection of typhoid and paratyphoid B vaccines respectively These vaccines were freshly prepared or stored for intervals of from one and one-half to three years Ten days later some of the mice in each series (one series received 500 million and the other fifty million bacteria of the vaccine) were tested with five, and an equal number with two fatal doses of the corresponding virulent cultures The same amount of protection was obtained with vaccines that were stored for from one and one-half to three years as with freshly prepared vaccines The amount of protection in most instances corresponded directly to the size of the immunizing dose

Prognostic Value of Cold Test in Pregnancy—Briggs and Oerting carried out the cold stimulus test on 233 consecutive patients entering the antepartum clinic From the family history it was found that ten patients had both a maternal and a paternal hypertensive background In these cases the existence of parental hypertension was corroborated by clinical examination Forty-four patients gave histories wherein one or the other parent suffered from hypertension It was in this group that cardiac and cerebral accidents were assumed to be of hypertensive origin In no instance was there any influence of the length of pregnancy on the cold test response The series was grouped according to their family history of hypertension In the group without familial hypertension only two patients were found to give an exaggerated response In those instances in which one or the other parent was hypertensive, twenty-one were normal reactors, ten were hyporeactors and thirteen were hyperreactors Of ten patients who gave a familial history of hypertension in both parents, all gave a hyperreactor response At the end of delivery only two individuals in the normal reactor group were found to be toxemic The toxemia in these instances was due to an underlying chronic glomerulonephritis No individual in the hyporeactor group gave evidence of toxemia that could be related to essential hypertension The hyperreactors in the group wherein no

familial history of hypertension was obtained showed no evidence of toxemia at the end of pregnancy Of the thirteen hyperreactors giving a history of hypertension in one or the other parent, ten had normal blood pressures when delivered The remaining three came to term with elevated blood pressures and one with signs of toxemia In the group in which both parents suffered from hypertension, all the patients were hyperreactors and nine of the ten patients showed definite alterations from normal at the end of gestation

Pancreatic Juice as Factor in Etiology of Gallbladder Disease—Wolfer believes that embryologic and anatomic evidence indicates that it is possible, in the human being, for a continuous pathway to exist between the pancreatic and biliary systems in a considerable proportion of cases Since the secretory pressure of the pancreas is greater than that of the biliary system, in the presence of obstruction at the papilla, it is possible for pancreatic secretions to mix with bile in the common duct There are many clinical examples proving the fact that the pancreatic juice may enter the gallbladder and that, associated with this phenomenon, necrosis of the gallbladder with or without a biliary peritonitis may exist Experimental evidence clearly indicates that the pancreatic juice may affect the walls of the gallbladder under variable conditions and produce different types of changes Under normal conditions the bile passes through the ducts to be emptied into the duodenum, some entering the gallbladder to be concentrated and later to be expelled into the common duct The pancreatic juice may enter the duodenum by a direct passage or may fuse with the bile in the ampulla Without stasis and with normal anatomic and physiologic mechanisms, even though the duct bile may be mixed with pancreatic juice, no pathologic changes take place in the biliary passages With low grade stasis, if the pancreatic juice content is low and no bacterial contamination is present, no changes may occur in the wall of the gallbladder If, however, the pancreatic juice content is higher, the stasis prolonged and possibly a low grade bacterial contamination present, changes may occur as described by Andrews, Goff and Hrdina When the concentration of pancreatic enzymes in the gallbladder bile is high, the pathologic changes produced will depend on complete or incomplete activation of the pancreatic enzymes in greater or lesser dilution in contact for short or long periods, sufficient time and concentration being necessary for necrosis The cause of selected cases of acute necrosis and acute gangrenous cholecystitis and also cases of chronic cholecystitis with or without stone can be found in a reflux of pancreatic juice into the gallbladder

Specific Serum in Treatment of Typhoid—Cookson and Facey administered Felix's antityphoid serum to seventy-three of 500 typhoid patients, the result of a milk-borne infection in a local outbreak in 1936. With a few exceptions the patients receiving the serum were the more severely affected ones. The majority received serum late in the course of the disease, in a considerable proportion of the cases the average dosage of 47 cc was too low and in a few simultaneous blood transfusion or intravenous saline infusion made it difficult to assess the results. These were considered in relation to effects on temperature and toxemia separately. The authors considered as an arbitrary standard the lowering of a previously high constant temperature within forty-eight hours of the injection of serum, the fall continuing for at least seven days. Effects on toxemia were accepted only when well marked and if evident within forty-eight hours. There was a favorable action on toxemia in fifty-four of the seventy-three cases. In a further eight cases improvement was noted within two to seven days after treatment. Seven of the serum treated patients died. A serum rash was observed in twenty-two of the seventy-three cases. A severe anaphylactic reaction was observed in only one. For sporadic cases or small outbreaks, when proper control is not possible, the evidence so far available warrants the administration of serum at the earliest possible moment and in full doses, irrespective of the severity of the disease. The Lister Institute recommends three doses of 33 cc of the concentrated serum for adult patients.

Diabetes and Tuberculosis—Dunlop suggests that the liability of patients having severe diabetes to develop tuberculosis should be constantly kept in mind. The possibility of this complication having occurred should always be suspected and excluded when for no obvious reason, a previously controlled diabetic patient begins to require larger doses of insulin to lose weight and to fail in general health. The danger is particularly present in patients who have suffered from hyperglycemic coma and in diabetic children. Such cases should be

examined at intervals for the specific purpose of excluding tuberculosis, young diabetic patients should be particularly excluded from association with open cases of tuberculosis. With early diagnosis of the tuberculosis and efficient treatment of the diabetes there is no reason to believe that diabetes will have an adverse effect on the tuberculous process. A high caloric, high fat, low carbohydrate diet with sufficient insulin should be used, and, if the case is otherwise suitable, artificial pneumothorax should be induced under sanatorium conditions whenever possible.

Emotional Factors in Health and Disease—Swanton suggests that the medical profession in general widen its outlook in the recognition of the significance of emotional factors in the incidence of both health and disease, that is, that there is a dual etiology. For a wider diagnosis one must make some effort to realize more clearly the colossal implications of the struggle in each individual between primitive human instinct and the claims of civilization. Often the physical side is the only important one from the point of view of diagnosis and treatment. Sometimes too the psychologic aspect is the obvious one to attack, the emotional maladjustment being too obvious to ignore, but in between these there is a vast range of conditions in which the diagnosis is vague, and ordinary treatment or treatment on purely physical lines is unsuccessful but for some reason the word neurosis is never mentioned. To be a little more specific, the profession has been very much concerned in the past with the seeds of ill health and but little with the soil. The author does not wish to suggest a psychologic explanation or causation for all illness but simply to issue a plea for the recognition of patients as psychosomatic unities and for the recognition of the multiple etiology of illness. The emotional lives of patients are as worthy of investigation and examination as their physical bodies. Every medical man should have sufficient knowledge of psychophysical interactions to help his patients from both points of view. He needs to know only a little of the general effects of emotional tension and to recognize those cases in which this tension exists. Fortunately a great many practitioners do this very completely without calling it psychology, but it would be a great help to the general public if the field of diagnosis were widened and new forms of treatment correspondingly devised. The profession might then aspire to take away some of the flourishing business of the herbalist, the faith healer and other irregular practitioners who occasionally disturb its peace. For undoubtedly these people often give to patients something which they do not get from their physicians—a crude attempt at a wider diagnosis and general human understanding.

Dactylitis from Pushing Back the Periungual Tissue

—Nicolas and Rousset observed lesions of the ungual matrix which are often caused by misunderstood manicure treatment and by dirty instruments. It often so happens that, after the infection of one finger, other fingers likewise become infected. At its base the epidermic fold that covers the nail is raised and gaping, it is reddened and oozes continually. It is more prevalent in women and may last for months or even years. Through manipulation with pushing and cutting instruments which are rarely cleansed after using an infection invades the superficial wounds and finds a favorable place for thriving and the formation of excrescences. When nail polish is then added it may increase or subdue the infection, depending on its contaminating or disinfecting ingredients. In accordance with the intensity of the inflammatory process and the depth of the lesions, the authors distinguish three clinical forms. 1 The purely inflammatory form, occurring in one or many fingers, assumes the shape of a periungual paronychia with redness, swelling, tension and thinning of the skin. 2 The suppurated form presents a degree of infection higher than the preceding and is essentially a paronychia of the periungual region or of the ungual matrix. It is also of longer duration and often causes complications. 3 The mixed form presents both preceding forms on different fingers. The treatment is directed against the pain and the inflammation with warm baths and moist dressings, while the patient is instructed to cleanse the wounds from two to three times a day with ether followed by a 1 per cent mercuric oxide ointment. A daily application of 2 per cent iodized alcohol will seep into the deep lesions. Excrescences should be cauterized or coagulated and in some cases the extraction of the nail may prove necessary. The practice of aseptic prophylaxis is advocated.

Skin Manifestations in Leukemia—Gate and Cuilleret describe three cases of lymphomatosis in which the cutaneous manifestations may obscure the clinical picture. The first is a case of typical leukemic erythrodermia which in the beginning looked like a psoriatic parakeratosis and later like a premycotic erythema. But the enlarged inguinal and axillary glands and the enormously increased leukocytes pointed to leukemic erythrodermia. The second case was characteristic of leukemic erythrodermia with general pruritus, scratch wounds and pyogenic dermatitis. But what mostly confused the picture were a number of hard nodules, especially on the forearms, which proved, microscopically, to be as many leukemic tumors. Lymphoid nests round the vessels clinched the diagnosis. The third case presented itself as a changeable dermatosis. It began with fever, enlarged spleen, micropolyadenopathy, slight lymphocytosis and cutaneous mucous lesions and gradually changed into an eczematous dermatitis. A biopsy revealed the peribuccal vegetations to be a simple papillomatosis which resisted all medication. Subicterus, loss of appetite, enlarged liver and spleen together with a general adenopathy completed the syndrome. The intention of the authors is to show that in spite of the atypical clinical picture the lesional polymorphism may lead to the notion of an obscure leukemia.

*Localization of Nervous Accidents Resulting from Insufflation of Therapeutic Pneumothorax G Poix and A Jacquet—p 745 Compared Experimental Toxicity of Some Antistreptococcus Substances B N Halpern and R L Mayer—p 747

Accidents Resulting from Therapeutic Pneumothorax

—Poix and Jacquet maintain that accidents from air emboli can happen only when the lungs are wounded and the blood vessels are invaded by the liquid or the air injected. Patients who died after pleuropulmonary interventions showed gas bubbles in the cerebral arterioles which were similar to those in animals that received a few cubic centimeters of air into their vessels. The authors therefore reject the theory of the

pleural reflex and accept that of air embolism. Over the right side of the heart there could be heard for some time an intense continuous gurgling sound accentuated during systole. These sounds gradually disappeared or became modified according to the patient's posture. In 1875 Couty showed the reason why the air accumulates in the right ventricle, others have demonstrated that from there the gas bubbles invade the lung capillaries and, returning to the left ventricle, may give rise to cerebral emboli. The authors have further observed that convulsions or paralyzes are situated mostly at the side opposite to the insufflation. This may be due to the topographic localization of the branches issuing from the aortic arch in accordance with the posture assumed by the patient at the time of the insufflation. With the patient in the ventral posture the gas embolus follows the posterior aspect of the arch and passes into the brachiocephalic trunk. This occurs also when the patient lies on his left side. Paralysis and convulsions develop on the left side. With the patient in the dorsal or ventral posture it is again the left side on which the accidents are mostly localized. In left pneumothorax and the patient in the right-sided posture the embolus enters the left common carotid artery and gives rise to right-sided accidents. If a left or right pneumothorax is insufflated below the clavicle or through the interscapulovertebral region with the patient in either dorsal or ventral posture, the embolus will invade the brachiocephalic trunk and the accidents are left sided. If the patient leaving his horizontal posture sits or stands up, the gas bubbles in the heart cavities may be liberated and may lead to aggravated or immediate accidents. In this manner may be explained late accidents or sudden deaths the moment the patient assumes an upright position. In accordance with the localization of gas emboli, vasomotor disturbances have been observed on the skin in the shape of erythematous blotches, anemic pallor, pallor and sensitiveness of the lingual mucosa and even amaurosis, betraying the presence of gas bubbles in the central artery of the retina. The authors recommend leaving the patient in the horizontal or even the Trendelenburg position the moment nervous accidents become manifest or as long as characteristic heart sounds are heard.

*Action of Liver Treatment in Experimental Toxic Anemia from Administration of Aromatic Substances D Campanacci and S Tosi—p 531 Crisis of Reticulocytes and Intensity of Anemia in Course of Malarial Treatment L Pontoni and S Motta Di Mauro—p 553

Descending Pleuro Abdominal Syndromes (Perivisceritis of Upper Crossroad of Digestive Tract Secondary to Pleuritis) G Pellegrini—p 557

Familial Addison's Disease G Borghini—p 587

Liver Treatment in Experimental Toxic Anemia—Campanacci and Tosi induced hyperchromic macrocytic anemia in rabbits by means of subcutaneous injections of hydroquinone, resorcinol phenol or thyroxine. The blood of the animals was rendered normal by the parenteral administration of liver extracts, even in the animals which were simultaneously given the toxic substance. According to the authors, liver extract neutralizes the toxins causing the anemia. The results of the experiments show the relations of experimental toxic anemia, induced by administration of aromatic substances, and hypochromic anemia in human beings, the importance of the toxic factor in the development of hypochromic anemia, and the antitoxic and antihemolytic mechanism of action of liver treatment in anemia. The mechanism was pointed out by Campanacci in 1928.

Value of Certain Laboratory Methods for Determination of Lipids in Blood Normal Lipemia Determined by Monasterio's Method C Campana—p 273

*Pharmacodynamic Action of Caffeine Intravenously Injected in Normal Persons and Hypertension R Martinetti and A Forconi—p 286 Protamine Insulin in Diabetes Results G Lolli and C Ballatore—p 299

*Preparation and Immunizing Value of Dysenteric Anatoxin D D Aniona M Valensini and E Falchetti—p 313

Pharmacodynamic Action of Caffeine—Martinetti and Forconi studied the effects of caffeine intravenously injected in normal persons and in patients suffering from hypertension

of different types. Immediately after the injection a transient increase of the arterial tension, especially the maximal arterial tension, and tachycardia take place. Both phenomena are more intense in hypertension than in normal conditions. The intravenous injection of caffeine administered to patients suffering from hypertension is followed by transient hyperglycemia and diuresis with increased elimination of urea and chlorides. According to the authors, caffeine when administered in proper amounts has a tonic action on the myocardium, increases diuresis with consequent elimination of toxic substances, and diminishes the spasm of the coronary arteries as well as intracranial hypertension. It does not lower blood tension in hypertension, except when the latter is caused by hyperepinephrinemia. Patients suffering from hypertension are hyperreactive to caffeine. The equilibrium of their circulation and chemical metabolism is unstable. Because of this fact, caffeine administered to the patients, especially if it is given in large doses, acts on the heart rather than on the peripheral vessels, with consequent increase of the blood pressure and lack of development of phenomena of peripheral vasodilatation.

Preparation of Dysenteric Anatoxin—D'Antona and his collaborators say that an anatoxin can be obtained from the toxin of *Shigella dysenteriae*, treated by Ramon's classic technic of addition of formaldehyde and exposure to heat. A good anatoxin is obtained from a good toxin produced by filtrates of liquid cultures or autolysates of solid cultures of *Shigella dysenteriae* of high virulence. The toxin from autolysates is more active than that from filtrates and the technic of producing it is simple. The derivatives of dysenteric toxin treated by formaldehyde are harmless and have flocculating and immunizing properties that make them actual anatoxins. Dysenteric anatoxin, if administered by subcutaneous or intravenous injection, produces immunity, especially if the autolysates used in preparing it contain fractions of the bacterial body. The condition of immunity of the vaccinated animals is proved by the results of the injections of dysentery toxin or of living virulent *Shigella dysenteriae*. The production of agglutinins in the blood serum of the animals vaccinated with anatoxin is scanty. A great amount of specific antitoxin was found in the blood serum of vaccinated horses. The authors advise anatoxin in the prevention of bacillary dysentery.

Buccopharyngeal Sepsis in Typhoid—According to Orgaz, the most grave buccopharyngeal ulcerations in the course of typhoid are those which develop in patients suffering from preexisting buccopharyngeal sepsis. The latter is the cause of the appearance of bacterial association and of the grave ulcerations of the buccal mucosa. The time of appearance of the ulcerations is unrelated to the stage of the disease. The ulcerations cannot be classified as symptomatic or late ulcerations or complications of typhoid. They are characteristic of the septic buccopharyngeal condition and are of a pyogenic nature and of fatal prognosis. Four cases are reported.

Histidine Treatment in Gastroduodenal Ulcer—Königsberg presents a critical evaluation of the histidine treatment in gastroduodenal ulcer. He shows that the experimental

studies on the basis of which Weiss and Aron introduced the histidine treatment cannot be applied to human subjects and that the patient with ulcer does not suffer from histidine deficiency. The protein splitting digestion ferments are not impaired in patients with ulcer and they are capable of extracting from their food all amino acids, including histidine. Thus the parenteral administration is superfluous and deficiency of amino acids cannot be regarded as an ulcerogenic factor. Histidine therapy is not a nonspecific irritation therapy, and an analysis of the clinical results, with the exclusion of all other factors that may play a part in the treatment, reveals that histidine therapy does not signify a great progress in the treatment of ulcer. The author shows that a rational therapy of gastroduodenal ulcer can be based only on a clear insight into the disease process. Even though the ulcer problem has not been completely solved, the author thinks that the studies conducted by Konjetzny and his collaborators provide a rational explanation of the pathogenesis of gastric ulcer, that is, they explain its development on the basis of a gastritis or gastroduodenitis and consider its treatment as primarily an internal problem. They recommend the administration of a colloidal silver preparation by means of a stomach tube and prescribe a bland diet. The pains are counteracted by means of atropine and belladonna. These medicaments are not intended as a means to reduce the acid secretion but rather as a spasmolytic.

Hiatogenic Dilatation of Esophagus—Strauss reviews his earlier studies on the genesis of the so-called cardiospastic dilatation of the esophagus, pointing out that among five such cases, which he examined post mortem, he detected three in which the dilatation and the mural thickening began two finger breadths above the cardia, that is, at the level of the esophageal hiatus. On the basis of this observation he suggests that in many cases the dilatation of the esophagus is caused by extra-esophageal changes, that is, by changes on the esophageal hiatus. He reasons that such cases should be referred to not as cardiospastic dilatation but rather as "hiatogenic" or "phrenogenic" dilatation of the esophagus. He also mentions hernia of the esophageal hiatus of the diaphragm. He says that a widening of the esophageal opening in the diaphragm (and perhaps hernia) is found chiefly in older persons, whereas a constriction of this opening and possible esophageal dilatation is found generally in younger persons. At any rate, the anamnesis of patients with esophageal dilatation often reveals that the disorder has existed for many years.

Serologic Study on Tuberculosis and Articular Rheumatism—Brandt and Kutschera von Aichberger report their experiences with serologic tests in 1,179 cases. Among this number were 305 cases of tuberculosis, fifty of tuberculous pleurisy, 100 of arthritis and 724 controls. All these patients were under hospital observation and subjected to thorough clinical examination for possible tuberculous changes. The serologic tests conducted by the authors were the so-called antigen-antibody reactions, that is, the complement fixation reaction with the antigen of Witebsky, Klingenstein and Kulm and Müller's conglobation reaction for tuberculosis. The intensity of these antigen-antibody reactions is a measure of the antibody formation. In tuberculosis, the reactions are in the beginning negative, they become positive after several weeks, but once they are positive they usually remain so as long as an active disease process exists. The reactions are weakened regularly if cure ensues but in progressing disease only rarely. The latter condition indicates an unfavorable prognosis, for according to Horster it seems to prepare for an

invasion of tubercle bacilli into the blood. By means of repeated tests it is possible to recognize changes in the immunity during the course of the disease. The simultaneous examination of the sedimentation reaction, of the tuberculin sensitivity and of Weltmann's coagulation band is of great help, for in this manner it is possible to gain a deeper insight into the immunobiologic development of the tuberculous process. The serologic antibody reactions are intensified by specific immunization, vaccination with living tubercle bacilli or tuberculin treatment. In persons without clinical signs of tuberculosis, the serologic antibody reactions for tuberculosis are generally negative. Exceptions to this rule are caused either by hidden tuberculous processes or by certain nonspecific processes. The serologic antibody tests are of great diagnostic value, because positive reactions direct attention to hidden tuberculous processes and negative reactions permit the differentiation of nontuberculous processes from tuberculosis. Exudative tuberculous pleurisy produces in the beginning negative tuberculous antibody reactions, but after several weeks they are positive. Acute rheumatic polyarthritis shows the same immunobiologic behavior. A temporary negative phase is always followed by a positive phase. This rule could be corroborated in all cases (twenty-two) that were subjected to repeated tests. On the basis of these observations and of the reports of others, the authors accept the theory of the tuberculous origin of acute articular rheumatism.

Drinking Child in Uterus—De Snoo points out that by sweetening the amniotic fluid the fetus can be induced to drink large quantities and that by injections into the amnion it is possible to influence the child directly by means of medicaments. He says that, although this treatment is of slight practical significance, it throws more light on the water exchange in the fetus, particularly in uniovular twins. He cites the case of a woman who was admitted to the clinic with severe hydramnion during the seventh month of pregnancy. However, the hydramnion disappeared and at the normal end of pregnancy two living, well developed uniovular diamnionial twins were born. The quantity of amniotic fluid was normal in both twins. In this case the water apparently had been eliminated toward the mother. Presumably the child drank the water, and after resorption in the intestine it was transported to the mother by way of the placenta. This case was not an exception, for after the author paid more attention to this phenomenon he repeatedly observed that the size of the hydramnion showed fluctuations or entirely disappeared during the fifth and sixth months. To be sure, these cases always concerned uniovular twins. The author thinks that this disappearance of the hydramnion is due to the fact that, with progressing differentiation of the two placentas, the production of amniotic fluid became lessened, in that the vascular communication between the twins was changed and that the disturbance in the circulation, which at first resulted from the reduction in villi and vessels, was again brought into equilibrium. The stasis in the child with the hydramnion was reduced in that the child drank more than was produced and both circulations reached their normal level. The author reasoned that it should be possible to reduce the amniotic fluid by sweetening it, thereby inducing the child to drink more. This was actually accomplished in a woman with hydramnion and narrow pelvis. Following the aspiration of 80 cc of amniotic fluid, the same quantity of a saccharin solution was injected. After this the hydramnion decreased in size the subjective complaints of the woman disappeared and her urine contained saccharin. Delivery followed three days later. The child was slightly edematous. The

blood of the umbilical cord and the urine of the child contained saccharin. The edema of the child had disappeared three days after birth. The author cites and discusses several other cases.

Granulosa Cell Tumors—Von Pallos describes three cases, one of which caused a temporary amenorrhea and two of which caused metrorrhagia. He suggests that the amenorrhea and the secretory phase of the endometrium are probably connected with the formation of lutein hormone by the lipid-bearing cells of the tumor. The hypertrophy of the uterus, the glandular cystic hyperplasia of the endometrium, the metrorrhagia, and the endometriosis in the third case are probably a result of the increased estrogen production of the tumor. The third case was noteworthy also because of the sarcomatous transformation of the stroma of the tumor. Although the granulosa cell tumors are at first benign, malignant degeneration often develops later. For this reason, patients with granulosa cell tumors should be kept under careful control, even after the operation.

- *Treatment of Spasmophilia by Means of Crystallized Vitamin B₁ T Widenbauer—p 82

Epidemic Benign Icterus in Children—Popovici-Lupa and Petrescu-Coman state that epidemics of benign icterus have been observed repeatedly among children. Following a review of the literature on this problem (beginning with Meissner's report in 1864) the authors report their own observations, which they made in the course of two epidemics, the first of which lasted from October 1932 to February 1933 and the second from September 1934 to May 1935. The majority of the patients belonged to the age group from 2 to 7 years. In all patients prodromal symptoms were observed, which persisted for from one to seven days. There were gastro-intestinal disorders (vomiting, colics and diarrhea), general indisposition and fever. In some of the children the fever reached 39 C (102.2 F). Several days after the appearance of the prodromal symptoms the icterus appeared, as a rule only in the form of a conjunctival icterus but occasionally also in the form of a mild icterus of the skin. There was oliguria, dark colored urine and whitish, hard feces. The tongue was coated. The fever usually subsided several days after the development of the icterus. The liver was always enlarged and sensitive to pressure. In many instances the hepatic enlargement persisted for a while after recovery. The spleen was likewise enlarged. Some of the children lost a considerable amount of weight. The disease usually took its course in from one to two weeks, but in three cases it persisted for from three to four weeks. The prognosis is favorable, all children recovered. The treatment consisted of rest in bed, with dietetic and medicinal measures. The diet contained chiefly carbohydrates, vegetables and fruit, methenamine was given in doses suitable to the age of the children. Search for a specific causal agent has not been successful as yet. Following a review of the literature on the problem of the causal agent, the authors say that the failure to discover a source of infection suggests the possibility of bacillus carriers. It is difficult to determine the exact length of the incubation period, but the authors observed that the majority of cases appeared from twenty-one to twenty-eight days after exposure. Others have observed shorter periods of incubation.

Treatment of Spasmophilia with Vitamin B₁—Widenbauer points out that spasmophilia is regarded by many as a manifestation of a deficiency in vitamin B₁ and has been treated with good success by giving yeast. However, since yeast contains also other important substances, such as provitamin D, the author decided to try a crystallized B₁ preparation. He treated ten spasmophilic children with one or two intramuscular injections of 400 pigeon units of crystallized vitamin B₁. In

all except two cases the spasmophilic symptoms disappeared after from twelve to seventy hours. In one case more time was required and in another the treatment failed. In four of the successful cases either no other treatment had been given or only symptomatic treatment in addition to the vitamin, in the other four viosterol had been given in addition to the vitamin B₁. The author hopes that the efficacy of vitamin B₁ will be tried and demonstrated in a larger material of cases of infantile tetany, for he found that its action is more rapid than that of viosterol.

*Genesis and Treatment of Vaginismus J Novak—p 880

Genesis and Treatment of Vaginismus—J Novak says that, whereas formerly changes in the vulva, the vaginal introitus and the hymen were regarded as the cause of vaginismus, it is now generally recognized that vaginismus is of psychic origin, that is, it is the manifestation of fear and aversion against sexual intercourse. To be sure, lesions of the vulva and of the vaginal introitus do occur, but they are usually the results of unsuccessful attempts at coitus. In this connection the author mentions tears, inflammations and a too narrow opening in the hymen. That these factors increase the vaginismus is understandable, but the fact remains that vaginismus is of psychic origin. A confidential discussion will usually reveal the cause of the aversion against coitus, but in some cases a thorough psychoanalysis will be necessary. The cause of the vaginismus must be considered in the treatment, for it is necessary to remove in both partners all the factors that cause the woman to have an aversion against sexual intercourse. The psychotherapy usually does not require psychoanalysis (in the strict meaning of the term) but can be accomplished by a tactful and understanding physician. He should insist on sexual abstinence until all lesions of the genitalia have disappeared. Local treatment should consist in the systematic introduction of Hegar's dilators, but it should never be painful.

Case of Periodically Recurring Pseudologia Phantastica G Pisk—p 908

Reduction of Mortality of Nurslings—Januschke and Larcher state that since the end of February 1936 the cases of bronchopneumonia and otitis have assumed extremely grave forms. While the external symptoms of otitis have disappeared, suppuration of the petrosa has advanced and finally the abdominal organs have become involved. There were symptoms of alimentary intoxication, severe fatty degeneration of the liver and acute appendicitis or peritonitis, and in four out of five cases death resulted. Whereas in the cases of pneumonia and otitis, which occurred during the preceding months, it usually had been possible to support the circulatory apparatus by the systematic administration of digitalis-cafeine until the organism had developed sufficient defense substances to kill the infectious organisms, the digitalis-cafeine treatment failed completely in these cases (occurring after February 1936). Later it was decided to employ in addition to the circulatory remedies substances that would stimulate the organs and tissues that serve bacterial defense. When this was done cure could be effected in all of eight cases.

*Combination of Simmonds Disease (Pituitary Cachexia) and Gee-Thaysen's Disease (Idiopathic Steatorrhea) C D de Langen—p 2896
*Prontosil in Quartan Malaria Y Van der Wielen—p 2905

Healing in Primordial and Flat Bones—After reporting the clinical history of a patient who died of osteomyelitis of the flat bones of the cranium, Roegholt compares the osteomyelitic process in flat bones and in primordial bones. He also compares the healing of fractures in these two types of bones in human subjects and in guinea-pigs. He reaches the conclusion that the flat bones and their periosteum react much more slowly than the primordial bones and their periosteum. Moreover, in the flat cranial bones there is a difference in reaction between the external and the internal periosteum in that the external one reacts even less than does the internal one.

Combination of Pituitary Cachexia and Idiopathic Steatorrhea—De Langen describes the histories of two patients in whom pituitary cachexia (Simmonds' disease) occurred with idiopathic steatorrhea (Gee-Thaysen's disease). In discussing these cases, he shows that the two diseases have a number of symptoms in common. Further, he cites investigations recently carried out by Verzar. This author demonstrated that fat resorption in the intestinal canal is influenced and regulated by the hormone of the adrenal cortex. In the discussion of related problems it is pointed out that fat diarrheas occur in various endocrine disturbances. Since it is now generally accepted that the anterior lobe of the hypophysis secretes an adrenocorticotrophic hormone which stimulates the activity of the adrenal cortex, the supposition is justified that the concurrence of the syndromes of Simmonds and of Gee-Thaysen is not an accidental one but rather the result of disturbances in the complicated interrelations between different endocrine organs. Disturbances in the fat resorption occur also in acromegaly, and nontropical sprue has been observed in patients of the acromegalic type. Finally attention is called to differences between nontropical and tropical sprue. The differences cited indicate that nontropical and tropical sprue are not identical to the extent that has been assumed in recent years.

Prontosil in Quartan Malaria—Van der Wielen reports the histories of two patients with dementia paralytica who were subjected to malarial therapy (quartan). The first patient had also a cystitis and this condition was treated with prontosil. It was found that, during the course of the prontosil treatment the plasmodia disappeared from the blood and the attacks of fever ceased. It was assumed that the prontosil treatment was responsible for this and it was decided to administer prontosil to a second patient who underwent malarial therapy on account of dementia paralytica. Here again the fever attacks ceased and the plasmodia disappeared from the blood. Although the two cases suggest that prontosil acts on the plasmodia of malaria, experiences on a larger material will be necessary to arrive at more definite conclusions. Moreover, the author recommends that tests be made to determine whether prontosil will act on the tertian type of malaria and on both types of malaria when contracted through bites.

NEUROLOGY—PAST AND PRESENT

CHAIRMAN'S ADDRESS

HENRY R VIETS, MD

BOSTON

The beginnings of neurology as a separate discipline of medicine are so clearly defined that one may say Neurology began with Romberg, a hundred years ago. His famous "propedeutic clinic" at Berlin, where systematic neurologic examination and clinical diagnosis were first carried out, was an active institution in 1837, and his textbook on nervous diseases, the first formal treatise on the subject, followed in 1840 and 1846. Almost contemporary in Paris that strange and interesting figure Duchenne of Boulogne was haunting the larger Paris hospitals, delving into case histories and unselfishly devoting himself to neurology and electrophysiology. An even more important Parisian figure was soon to follow in Charcot, who created the greatest neurologic clinic of modern times and gave lessons in visualization which few students could ever forget. Marie and Dejerine carried on the great French tradition even to our times, as did Erb in Heidelberg, following the footsteps of Romberg. In England, Hughlings Jackson and Gowers, building on the sound framework of the German and French schools, brought to virtual completion the foundations of structural clinical neurology as it is known today. In America, Weir Mitchell, physiologically trained by Claude Bernard, Dana, with his textbook of 1892, and J J Putnam added new knowledge to neurology and pointed the way to the advances that were to take place in the twentieth century. Thus by 1900 neurology was well established in most medical schools and hospitals. Although few professorial chairs were founded and neurology was largely taught by the department of medicine, its place in the hospitals was recognized, at least in the outpatient department, and the neurologist was no longer called "the electrician," as he was at the Massachusetts General Hospital in the eighties.

At the turn of the century, therefore, most of the intrinsic nerve and spinal cord diseases were known, the larger tracts had been identified, the motor cortex had been partly demonstrated in animals, and gross anatomy and pathology were beginning to be understood. Brain and spinal cord tumors were soon partly localized, and at least one surgeon had removed a meningioma from the brain, although in opposition to the advice of the attending neurologist. Expert in diagnosis, the neurologist in 1900 was equipped with only a few methods of treatment. Iodides, mercury and bromides were almost

his only defense, and many believed that a brain tumor could never be successfully removed. The only exception was with regard to the surgical treatment of peripheral nerve injury. In this field much had been learned since the American Civil War. In such a state of relative therapeutic nihilism, however, clinical neurology was nearly at a standstill. After a few years of stagnation, just before the Great War, it received a new stimulation from three important sources, all from outside its narrow specialism of clinical neurology.

STIMULATION OF CLINICAL NEUROLOGY BY DISCOVERIES

First to awaken neurology was the discovery of a specific test for syphilis by Wassermann, the identification of tabes dorsalis and dementia paralytica as syphilitic diseases, the diagnosis by examination of the cerebrospinal fluid, and the advent of an astounding pharmaceutical in arsphenamine. Neurologists stirred themselves, lumbar punctures were done, usually with complete surgical regalia, and intravenous treatment was started with quarts of diluted arsphenamine. The younger men soon became adept with their hands and used the new tools with ease, much to the astonishment of their elders. Much of neurosyphilis was allowed to slip away, nevertheless, into the hands of the dermatologists in the "South Medical" department, as it was called, at least at the Massachusetts General Hospital, in those days. Neurology needed other stimuli to keep awake and one, or really two, were soon to follow.

In Liverpool, and later in Oxford, neurophysiology was rapidly being pushed forward by the greatest master of our times, Sherrington. In his "Integrative Action of the Nervous System," published in 1906, much unplowed ground was cultivated and a new, dynamic concept of the reflex functions of the nervous system was set forth. To his laboratory came a pupil from America who ultimately was to establish securely a new branch of medicine, neurosurgery. Inspired by Sherrington and not unmindful of the contributions of Horsley and his teacher Kocher, Cushing had so far advanced the art of neurosurgery by 1914 that surgical treatment was soon offered, and most gratefully accepted, by about 10 per cent of our patients. Here at last was the therapeutic stimulus so badly needed by neurology. Sherrington and Cushing, leading a great band of followers, revolutionized neurology. Without them should we be much further along today than we were in 1914? The force given by these two physicians slowly overcame the inertia of a nearly static part of medicine, which had tended to make neurologists into expert diagnosticians but feeble therapists. Sherrington added the fundamental research point of view by continually augmenting our knowledge of the function of the nervous system and stimulated a host of like minded pupils. Cushing, with his associates and pupils, although at first almost single handed, brought

From the Department of Diseases of the Nervous System Harvard Medical School.
Read before the Section on Nervous and Mental Diseases at the Eighty-Eighth Annual Session of the American Medical Association Atlantic City N J June 11 1937

to neurology a method of treatment which we now find useful in nearly half our patients. Finally came the World War, and after 1919 neurology, taking on its present form, grew rapidly—and the end is not in sight.

PROBLEMS ARISING OUT OF THE WAR

The war brought a host of problems which overtaxed the capacity of the then available supply of neurologists and the few trained neurosurgeons. War neuroses and peripheral, spinal cord and brain injuries were so numerous that, failing neurologists, psychiatrists, physiologists and even psychologists were pressed into action and general and orthopedic surgeons were forced to handle the strange material. Infectious diseases, especially epidemic meningitis, soon tested the ingenuity of the neuropsychiatric division of the medical corps in this country, only to be followed here and overseas by an overwhelming disease, lethargic encephalitis. The lack of adequately trained men was felt on every hand and once the war was over, in 1919, many schemes were proposed to establish neurologic institutes and revamp the inadequate teaching of diseases of the nervous system in our medical schools. There was much discussion, but finally most of the schemes were abandoned. The pressure, however, was too great to be ignored and gradually adjustments were made in both the development of clinics and in teaching

GROWTH SINCE THE WAR

It is not my province to give a complete outline of all the changes that have taken place in neurology since 1919. To many neurologists they have been part of their daily life. The great schools of Philadelphia and New York have been continued, as have those of London, Berlin and Paris. The school in Boston, never perhaps so important as those in Philadelphia or New York, has gradually become revolutionized and it is about this development that I wish to speak briefly, using it as a basis to illustrate the whole subject. I think our experiences in Boston have not been unusual, in spite of the rapid growth in interest shown by the number of workers engaged in research and teaching. There has been, moreover, an expansion of the clinical facilities, and this change at one institution, the Massachusetts General Hospital, may be used to make my point. A similar story might be told of the changes at the Boston City Hospital.

Twenty years ago, two beds in the medical service of the Massachusetts General Hospital, with none definitely assigned to neurosurgery, were considered sufficient for a general hospital of 300 beds. The outpatient department was the home of neurology. Occasionally spinal cord or brain tumor was suspected in a patient and thus use for the two beds was sometimes found. This small unit, not always kept full by the neurologic department, has now grown into an independent one of twenty-four beds, one half given to neurology and the other half to neurosurgery. Residents, house officers, a neuropathologist, a cerebrospinal fluid technician, research physicians, social workers and third and fourth year students have joined the visiting neurologists and neurosurgeons to make up a coordinated unit, diagnosing and treating more than 500 patients a year, one fifth of whom proved to have tumors of the brain. This ratio, I suspect, would not be found in many other hospitals, particularly hospitals that draw on a single city for their supply of patients. It should be pointed out, nevertheless, that nearly half of the patients who enter the neurologic

ward at the Massachusetts General Hospital do not leave without some sort of surgical treatment. The neurologist and the neurosurgeon, therefore, must in the future go hand in hand and the relationship is bound to be closer between neurology and neurosurgery than it ever was between neurology and psychiatry.

The clinical neurologist, treading his way carefully in private practice so as not to disturb his status as a "nerve man" and thereby lose the largest part of his practice with the psychoneurotic and the borderline psychotic, must become in the future, nevertheless, either a psychiatrist with neurologic leanings or a clinical neurologist, closely bound to neurosurgery, neurophysiology and the fundamental sciences of neuro-anatomy and neuropathology. The latter individual would appear to be the proper person to head a neurologic department in a general hospital or medical school. In some instances, in recent times, the neurologic director of a department has been replaced by a neurosurgeon, a neurophysiologist or a neuroanatomist. If such is the case, restraint may be needed to prevent the individual interests of the director in his special field overspreading the whole clinic. As broad as may be the training of a neurosurgeon, one cannot help but view with a little apprehensiveness the effort being made to replace the neurologist by an active surgeon as head of the department. Neurosurgeons may be good neurologists, as certainly the best of them are, but their main interest must necessarily be in surgery and not in the larger clinical field of neurology. The ideal arrangement would be for the man with the broadest outlook to head the department and to have his neurosurgeon on a practically equal footing with himself in the division of the number of patients. There may be exceptions to this, for the man, whatever his departmental label, is more important than the chair in which he sits.

In the year 1936 about 500 patients were discharged from the combined neurologic and neurosurgical services of the Massachusetts General Hospital. While in the hospital, 300 patients were directly under the care of the neurologic staff, while the other 200 fell to the neurosurgical department. It is worth noting that something over 100, or 20 per cent of these patients, suffered from brain tumor and another 5 per cent from spinal cord tumor. Even though the clinic does not admit patients with acute brain trauma, it will be seen nevertheless that 30 per cent of the patients require surgical treatment for neoplastic disease. If there is added to this the patients operated on for various types of chronic nervous disease, repair of peripheral nerves, the diagnostic tests such as ventriculography, and those requiring operations, curative or palliative, for pain, one readily sees that nearly half the work in an active neurologic ward is done by the surgeon. Thus, I am sure, is in great contrast to the situation twenty years ago.

In hospitals in other cities the situation, however, is quite different. The medical department still directs neurology, and neurosurgery, if there is such a separate division, is under general surgery. The time has come when the facilities offered not only for diagnosis but for treatment of nervous diseases is of such importance to the general public that special departments with an adequately trained personnel must be more widely available in this country. Too many patients still enter the hospital with tumors of the brain, already blind from long standing increased intracranial pressure or having had one or possibly more abdominal operations.

prior to the disclosure of a spinal cord tumor as the cause of their discomfort. It is no longer possible for the general physician or surgeon either to diagnose or to treat at least one half of the neurologic cases that appear in his practice. He must have help, and help should be easily available.

If surgical treatment is used on half our patients, we must not neglect the other half of a neurologic group. There is much to be offered now in the treatment of meningitis and of the acute infections of the nervous system, those caused by viruses, and some of the more intrinsic degenerative conditions. If the neurologist keeps at least part of his patients with neurosyphilis, a wide field of therapy is offered and practical cure of half of them is not unlikely. There are, moreover, many new drugs available, such as prostigmin for myasthenia gravis, which are slowly changing our whole therapeutics.

RESEARCH AND TEACHING

Finally, we have additional duties to perform, at least those of us associated with clinics in the larger medical units. Not only must we treat our patients but we have the burden of advancing the subject by research and passing our knowledge on to a future generation by teaching. Much of our research originates outside the clinic, particularly in the laboratory of the neurophysiologist. From Sherrington's laboratory and in this country from the workshop of his illustrious pupil Professor Fulton of the Yale University School of Medicine have come many of the ideas with regard to the function of the nervous system which we have been able to apply to clinical neurology. Problems, too, are continually presented from other clinics in a great hospital by, for instance, the ophthalmologist, the aurist, the orthopedic surgeon and the roentgenologist. The latter, by his expert technical advice, has been able to disclose so much of the bony structure surrounding the nervous system that our diagnostic acumen has been greatly increased. Ventriculography and the more useful encephalography have now become routine diagnostic procedures, augmenting the older examinations of the cerebrospinal fluid and blood. Electroencephalography, the newest product of the laboratory is gradually entering the clinic, with possibly the greatest beneficial value of any advance made in neurophysiology of all time. Even to evaluate the products of the research laboratory requires of the neurologist a wide training in neurophysiology and its associated branches. The neurologist, moreover, should be able to guide the surgeon into profitable paths of therapy—something that has not always occurred in the past. Advancement, therefore, in a neurologic clinic which takes advantage of all the research available can be made only under the guidance of a physician with a wide vision. Fortunately, the neurologists in this country are not by any means taking their positions lightly, and there is evidence on every hand that they are assuming their duty with a steadfast purpose and unselfish devotion. The neurologic clinic in the future will justify itself only if it incorporates physiology, pathology, chemistry and physics in research problems. Similarly, the clinical neurologist must correlate and use all the laboratory data that present themselves from year to year, with that rare and most elusive of phenomena, good clinical judgment.

In addition to research and the development of the modern clinic the teaching of neurology is undergoing a revolution in our medical schools. There is much,

however, still to be done in this field. When one finds that only sixteen of our seventy-five credited medical schools have separate departments of neurology and that only twenty more teach neurology under a combined department of neuropsychiatry, one wonders how much of modern neurology reaches the medical student in the other thirty-nine schools. Even in the sixteen schools with separate departments the number of hours given to clinical neurology is extremely variable. Two schools head the list with 116 and 120 hours. Two give only forty and forty-two hours. The average time of instruction, usually given in the third and fourth years of the course, is slightly over sixty hours. Most of the larger schools have abandoned didactic lectures and only the smaller hold to strict textbook instruction, chapter by chapter. Teaching is best carried out by clinics in the second and third years, section work in an outpatient department in the third year, and clinical clerkships in the fourth year. This has been the scheme of teaching at the Harvard Medical School since the war and is now almost universal in the larger schools. One notes with satisfaction the number of fourth year students at the Harvard Medical School applying for the clinical clerkships, still a voluntary course. Nearly half of the class will take such a course during the next year. A few years ago the number of applicants was only about 10 per cent of the class. Thus we have, in instruction given as the result of voluntary application on the part of students, another index of the growing interest in neurology.

Analysis might be made also of the number of hours given to instruction in clinical neurology in the other twenty schools, where neurology is combined with psychiatry in one department. Such a tabulation from school catalogues is by no means easy, as often the hours are not separately listed, nor are the courses distinct enough to evaluate what part of the course is given over to neurology. One is unimpressed, however, by the fact that psychiatry takes up the larger part of the time, especially in schools where the departmental teaching is almost entirely limited to instruction given in a state hospital for mental diseases. This is the case in some of the smaller medical centers.

In a few medical schools, however, a strong psychiatric department takes over the brunt of the teaching of neurology—perhaps a sound scheme, but one that must leave the student woefully lacking in some of the important features of neurologic training. If one considers that one fifth of the patients in a neurologic clinic have tumor of the brain, how many such patients are likely to be seen in a psychiatric ward? In other schools neurology has been so divided that the department, as such, is not to be found in the school catalogue. Neurosyphilis is in the hands of the syphilologist, neurosurgery is taken over by the surgeon, the neuroses and psychoses fall to the psychiatrist, and all the rest of neurology to the department of internal medicine, save possibly for a few epileptic patients lost in the outpatient department. Can neurology hope to advance with such dispersion of her interests? That, of course, depends in part on the caliber of the men in the various teaching departments. Many internists are good neurologists or have been in the past. Nearly one fourth of Osler's early papers were neurologic in character and it is said that one third of his consultations dealt with obscure neurologic diseases. It seems unlikely, however, at present, with the rapid advancement in other fields of medicine as well as in neurology, that an internist would ever have the time to learn

the complete technic of modern neurologic diagnosis and treatment. Encephalography, for instance, one of our most important diagnostic procedures, will not, in all probability find its way on to the medical wards, as has the more simple maneuver of lumbar puncture.

GROWTH OF SOCIETIES

Each year makes clear the ever increasing complexity of our position and the necessity for a continuation of the control of our own destinies as a unitary part of a great hospital or medical school. Had we not already done so in the past, should we have seen, in the last twenty years, the remarkable growth of the American Neurological Association and this section of the American Medical Association? In 1916, when this section was called to order at Detroit, a mere handful of neurologists and psychiatrists met in a small school-house adjacent to the main meeting hall. At that time there was serious talk of abandoning the section or merging with the Section on Practice of Medicine. The secretary, moreover, in those days, only twenty years ago, had to write to men urging them to present papers. In my last three years as secretary, from June 1934 to June 1936, the situation has so far reversed itself that the handful at times had grown to 200 and only one in three or four of the applicants for a place on the program could be accepted. Witness too the vast amount of research which is reflected in the sixty volumes of *Brian*, the eighty-five volumes of the *Journal of Nervous and Mental Diseases*, and the thirty-seven volumes of the *Archives of Neurology and Psychiatry*, and the enthusiasm shown at the first International Congress of Neurology at Berne in 1931 and at the second in London in 1935 with forty-two countries represented at each and from eight to nine hundred physicians registered.

One notes also the growth and importance of the local neurologic societies, their helpful place as a "trying out" center for papers later to appear at the national association meetings, the development of the neurologic institutes in the larger cities, the publication of collected reprints, case books, smaller journals, such as the one recently inaugurated at Los Angeles, and the year books with their invaluable summaries. Particular attention should be called to the review of neurologic and psychiatric literature, so long carefully edited by Dr. Bassoe and now in other, but equally capable, hands. The yearly publications of the Association for Research in Nervous and Mental Diseases again reflect the interest shown in neurology.

The number of individuals, moreover, working on diseases of the nervous system has become almost appalling. From a scant half dozen physicians gathered together in Boston in 1920, recently eighty-five physicians doing work in psychiatry, neurology, neurosurgery, neuro-anatomy, neurophysiology and psychology met to honor one of their leaders. The trend is noted in the number of students entering the field and the application for certification by the Examining Board of Neurology and Psychiatry. Perhaps the most important sign is the large number of young men and women seeking knowledge in our laboratories, schools and hospitals. For the older neurologists this has come as a great challenge, for these young people crowd in on us and demand the best of training and the largest scope for their potential abilities. We must uphold those standards set by Romberg, Charcot, Sherrington and Cushing if we are to keep faith with our predecessors and do our duty to those who come after us.

6 Commonwealth Avenue

ACTIVE AND PASSIVE IMMUNITY AND PORTAL OF ENTRY IN POLIOMYELITIS

JOHN A. TOOMEY, M.D.

CLEVELAND

Attempts have been made to render *Macacus rhesus* monkeys immune to poliomyelitis by injecting the living virus,¹ killed virus,² virus attenuated by heat,³ virus attenuated by drying,⁴ or virus attenuated by various chemicals (solution of formaldehyde,⁵ sodium ricinoleate,⁶ aluminum hydroxide,⁷ phenol⁴), by injecting weak strains of living virus⁴ or by injecting higher dilutions of more virulent strains.⁴ These antigens have been introduced percutaneously,⁴ intracutaneously,⁸ intratesticularly,⁹ intrasplenically,¹⁰ intracerebrally,¹¹ by way of the gastro-intestinal route¹² and by spraying the nose.¹³ Active immunization has also been tried by injecting virus in combination with immune sera obtained from monkeys,¹⁴ sheep,¹⁵ horses¹⁶ and human beings¹⁷ or by injecting neutralizing sera first and then virulent strains of the virus.¹⁸

The evidence on active immunization is confusing. Animals which have been immunized are presumed to have humoral immunity if virus-neutralizing antibodies are observed in their blood sera and a tissue type of immunity if they survive subsequent intracerebral injections of the living virus. Doubt has been expressed as to whether neutralizing antibodies (humoral) are true measures of immunity, since even though animals may have neutralizing antibodies and a high titer, they usually succumb to the disease when subsequently inoculated intracerebrally with poliomyelitis virus.

Certain tissues of the body have no resistance to an infection. On the other hand, certain tissues of the same host are highly resistant to the same infection. The virus of rabies has its portal of entry through the broken skin, and animals and men are immunized against this virus by subcutaneous injections, after which neutralizing antibodies may appear in the blood serums. Animals thus immunized are protected against the rabies virus when inoculated intramuscularly, but despite previous active immunization procedures some animals succumb to minute amounts of virus if subsequently inoculated intracerebrally.¹⁹

Protection against disease is usually only relative, rarely absolute and often easily diminished or lost. In a general way, natural or acquired immunity could be defined as that amount of resistance possessed by the host that protects him against the ordinary exposure dose at the usual portal of entry. In the past, tests of tissue immunity and general resistance against poliomyelitis have been made by introducing the virus intracerebrally or intranasally. When a potent strain of virus is introduced by way of these portals of entry, paralysis of at least some muscle groups will appear in animals that are otherwise naturally immune, but more likely massive quadriplegia will develop, which is often followed by death. Animals rarely escape the disease when a virulent strain is used. Since but few human beings get the disease although many are exposed and since abortive types without paralysis are said to be common, one wonders whether it is logical to test protection by methods that produce paralysis or quadriplegia in every animal used.

Although it has been claimed that immunity has been brought about by inoculating animals with chemically treated virus, it is not certain from reading the reports whether animals thus immunized have been other than merely inoculated with live virus to which some chemical had been added. When living virus has been shown to be attenuated or actually killed, it has lost most of its ability to immunize actively.²⁰ After one reviews the literature, two points seem clear. First, artificial immunity may be established against poliomyelitis if the living virus is injected as the antigen,¹ second, many monkeys acquire the disease during this process of active immunization.

Few children contract poliomyelitis, of these, few have massive paralysis and still fewer die. Yet despite the paucity of cases, the relatively low morbidity and the low mortality rates, such great fear is had for this disease that the use of any efficient method of vaccination against it would have widespread and immediate use. Since there is no way to distinguish susceptible persons from those who are immune and since the factors which predispose toward the disease are unknown, it is obvious that vaccine antigens must be safe. Thus they cannot be viable, and, paradoxically, if they are not viable they seem to be of no value. In fact, not only may it be inadvisable from a practical standpoint to immunize actively with virus antigens but it has been suggested that such vaccines may even be dangerous to human beings.²⁰

THE PORTAL OF ENTRY

If local tissue immunity develops at the site of frequent exposure to noxious materials, then in the study of any disease a knowledge as to the portal of entry

becomes of primary importance in order that one may understand the methods of host protection and immunity. Nature needs no special protection against virus in the brain and cord, covered as they are with thick bone and dura. Hence, intracerebral injections are no gage of either resistance or immunity, since an animal amply protected at the normal portal of entry might easily come down with the disease after this test.

Most American research workers in the field of poliomyelitis consider the first and thirteenth nerves the avenues by which the virus enters the body, notwithstanding the fact that it is not easy to recover the virus from the nasal passages of either man or animal and notwithstanding the fact that to produce the disease in monkeys when the intranasal route is used the nose sometimes has to be prepared or large amounts of from 5 per cent to 10 per cent virus must be carefully instilled into the nostrils for a few days. If the olfactory area is the place where the virus enters, then the virus would have to be breathed in with either the dust or the moisture or from the breath of other individuals. The last possibility does not seem likely, since monkeys never contract the disease from each other nor has a second case ever developed in our contagious wards. (The recent Los Angeles epidemic seems to be the only exception regarding obvious hospital contagion.) In a few experiments I have found that monkeys remained well even after breathing for a short time while a 10 per cent virus vapor suspension was sprayed in their faces.

It has been inferred that after the olfactory connections were severed the disease was not produced when virus was injected intravenously. There is no evidence that the disease is spread by way of the blood stream but, quite apart from this, these experiments have been repeated and it has been found that, when proper doses were used, section of the olfactory bulb did not protect animals after virus was injected intravenously.²¹

To explain why poliomyelitis develops in animals after intravenous injection, it has been suggested that the virus thus injected is excreted onto the nasal mucosa and then reabsorbed by the first and thirteenth nerves, after which the animal gets the disease. That blood vessels experimentally surcharged with the virus may excrete it via the gastro-intestinal tract, the upper end of which is in the stomadeum in the region of the first and thirteenth nerves, and that the virus may even be isolated occasionally from the nasal areas of these animals is admitted. Inferentially, however, the conclusion has been broadly drawn from these and other experiments that if the olfactory area could be blocked the human disease could be prevented. Hence, this area has been sprayed with chemicals as a prophylactic measure on the theory that if it is the portal of entry then spraying it with such chemicals will prevent infection at that point and therefore prevent the disease. Such procedures should and do prevent the experimental disease when the virus is subsequently introduced intranasally, since they prevent the approximation of axis cylinder and virus. However, such procedures (the administration of 1 per cent zinc sulfate intranasally) do not prevent the experimental disease from occurring after a sufficient amount of virus is introduced intravenously,²² nor do they prevent the production of the disease when the virus is introduced by way of the gastro-intestinal tract.

Sicard²³ suggested that the virus spreads from the gastro-intestinal tract to the cord by way of the sympathetic fibers. Wickman and even Harbitz and Scheel first thought that the disease must have its entry through and spread from the gastro-intestinal tract. The gastro-intestinal tract is often involved before somatic paralysis appears.²⁴ Reflex changes similar to those which appear in persons with typhoid fever occur.²⁵ The height of the spring and fall curves of the disease occur about the same time as those of typhoid fever, a gastro-intestinal disease.²⁶ Many early symptoms of poliomyelitis are referable to the gastro-intestinal tract. The disease can spread along the sympathetic fibers from the intestine.²⁷ The virus acts differently when injected by way of the gastro-intestinal tract than it does when injected by any other route.²⁸ When the gastro-intestinal tract is disturbed, paralysis is produced almost immediately when the virus is injected intracerebrally.²⁹ When either the virus or enteric toxins are injected intracerebrally nothing happens for days, but when enteric toxins and the virus are combined and injected, paresis or paralysis may occur immediately.³⁰ The agglutinin titer of the blood serum against enteric organisms is disturbed in this disease.³¹ In short, the clinical symptoms of the disease are best understood if a spread is presupposed along the sympathetic, parasympathetic and chorda tympani fibers to the lumbar, cervical and bulbar areas of the cord³² from a portal of entry in the gastro-intestinal tract.

METHODS OF OBTAINING A PASSIVE IMMUNE PRINCIPLE

Many efforts have been made to obtain an efficient passive immune principle. To that end, horses,³³ sheep,³⁴ monkeys,¹² guinea-pigs, rabbits, dogs and goats³⁵ have been immunized with suspensions of virus and the serums of these animals tested for their neutralizing values, with variable results. Artificial serums have usually failed to protect animals that had been previously or simultaneously inoculated intracerebrally with the test virus.

Convalescent human poliomyelitis serum has been used prophylactically and therapeutically,³⁶ and its value has been questioned not only on clinical grounds, but because it failed to immunize animals passively. It has been stated that the virus was fixed in the neurons and that human poliomyelitis convalescent serum might not be able to destroy it there.³⁷ It was likewise thought that the pathogenesis of the disease precluded possible beneficial effects of serum therapy, "since serum would have great difficulty in reaching and penetrating in through the central nervous system, and it could not dislodge the virus apparently fixed to nerve cells and thus prevent further propagation."³⁸ It is fairly certain that controlled clinical and experimental studies have shown that convalescent serum is not very efficient in the treatment of preparalytic poliomyelitis.³⁹ As a result, the opinion is general that neutralizing antibodies are no indication of immunity to experimental poliomyelitis and that passive immunity in the human being is nearly worthless, and convalescent serum is employed only on the basis that it can do no harm and that it may do some good. It has even been intimated that such serum may be harmful.⁴⁰

The fact that animals die of the disease even after treatment with potent serums when the infecting dose is delivered intracerebrally or intranasally does not necessarily mean that the animals lack immunity. Definite immunity may be demonstrated if the infecting dose is delivered at the proper portal of entry. The only animals that are protected from the effects of subsequent intracerebral injections are those that have recovered from a massive attack of the disease following a previous intracerebral injection or intranasal instillation of the virus or following active immunization with multiple subminimal doses elsewhere, and even these may develop the disease if the doses of the homologous virus administered the second time are massive in comparison to those ordinarily used to produce the disease.⁴¹ Even here, immunity, although tissue in character, may be relative.

The technic that I have used in producing the disease by the gastro-intestinal tract has been considered drastic, but even so the clinical disease as it appears in the human being has been reproduced in the monkey by these drastic procedures, and they have provided definite cleartest tests of protection. A normal monkey is not easy to infect by the gastro-intestinal tract. In fact, the normal monkey is immune to poliomyelitis unless the virus is administered artificially (e.g., injected intracerebrally, subserosally or between clamps into the intestine or instilled intranasally). However, an animal can be made so susceptible that even my drastic methods need not be employed, and the disease can be produced merely by placing the virus in the intestine.⁴²

I have mentioned elsewhere the belief that the spread of virus is usually stopped in normal animals by some factor found in the white and not in the gray fibers.⁴³

This seems incongruous since it has been shown that virus spreads over the axons of both medullated and nonmedullated nerves, although medullated nerves must be irritated before infection occurs. The disease was easily brought about some years ago when virus was injected into the sciatic nerves, but subsequent consistent failures brought to light the fact that there was some difference between the animals then used and the animals formerly used.

Probably the difference was due to the fact that the diet of the earlier group was devoid of vitamin D and, since later animals were fed viosterol, and thus possibly had better myelinated nerves of a high cholesterol content, it might explain why the more recently acquired animals did not contract the disease when inoculated peripherally.

The difference in the solid elements between medullated and nonmedullated nerves is chiefly in the cholesterol content, it is high in medullated (35 per cent) and low in nonmedullated fibers (0.7 per cent).⁴⁴ Cholesterol adsorbs or destroys poliomyelitis virus.⁴⁵ When rickets is produced in rats by lack of vitamin D, the nerve myelin becomes involved, since in these animals a foamy condition of the myelin sheath appears, probably the result of edema of the neurokeratin framework.⁴⁶ When rickets is produced in monkeys, probably the nerve myelin and its cholesterol content become involved and the virus is not adsorbed or destroyed. In any event, it is a fact that the disease is easily produced in such animals.⁴² On the other hand, when monkeys have had plenty of vitamin D and inferentially have plenty of cholesterol and good myelinated nerves, the disease cannot be produced via the gastro-intestinal tract. The subcutaneous area of normal skin has a high cholesterol content (19 per cent), and from 750 to 1,100 mg may be found in the total blood volume of an adult. Suggestive indeed in view of certain experiments on blood is the fact that the cholesterol content is increased during pregnancy. Suggestive likewise is the fact that massive amounts of virus must be injected into the blood stream before the disease is produced. Suggestive likewise is the fact that massive amounts of dihydrocholesterol (coprosterol and B-cholestanol) and cholesterol are contained in the normal intestine, which conjugated with virus could easily inactivate it and prevent infection from occurring.

If virus enters by way of the normal gastro-intestinal tract, it might go into colloidal equilibrium with the free cholesterol elements contained in the intestine and be destroyed there. It could also be absorbed by the nerves, but spread to the cord could be prevented by the cholesterolized white fibers in persons with well myelinated nerves, in some persons the virus may not be adsorbed because of deficient myelin, and it could spread over the sympathetic and parasympathetic chains, along nerves that possibly have been previously sensitized to enteric toxins and that have direct communication from the intestine to the lumbar, cervical and bulbar areas.

Thus there might be little or no marked production of neutralizing antibodies if the mechanism of primary defense was carried out in a healthy myelinated nerve, and primary protection would be merely a detoxifying adsorptive colloidal phenomenon. If, however, nerve fibers were diseased or poorly medullated virus might

spread along nerves to cells of origin, causing destruction followed by inflammation,⁴⁶ and neutralizing antibodies might be formed. In experimental work neutralizing antibodies were found to be effective in preventing the disease in monkeys when the virus was introduced by way of the gastro-intestinal tract,⁴⁷ and when this portal of entry is used experimentally it will be found that neutralizing antibodies are a good index of immunity. Since nature heals with the production of antibodies, even though they are quantitatively variable, it still seems logical to try to produce an anti-poliomyelitis serum.

At present there is no evidence of a controlled nature that convalescent poliomyelitis human serum has any value in the treatment of the disease. Certainly there is no reason why it should be given to exposed persons. There is likewise no controlled evidence that convalescent serum will abort an attack of poliomyelitis. A physician therefore who does not use this therapy does not withhold a beneficial procedure from his patient. Before this therapy is discarded, however, it might be wise, as Kramer⁴⁸ suggested, to ascertain if it has any worth when used in massive amounts in the preparalytic stage of the disease.

Since this article was written, Levinson⁴⁹ has reported that he has used massive amounts of convalescent poliomyelitis serum in the treatment of preparalytic cases with good results.

3395 Scranton Road

ABSTRACT OF DISCUSSION

DR JOSEPH YAMPOLSKY, Atlanta, Ga. Dr Toomey has attempted to give an evaluation and a review of the literature on the problems of the active and passive immunity in poliomyelitis. It is apparent that, although 80 per cent of the population seem to possess a natural immunity, the devastating and almost immediate effect of this disease in a few of those who do not possess this immunity becomes at times alarming. The use of chemical agents sprayed intranasally and the injection of Kolmer's vaccine as well as Brodie's vaccine have especially come to our attention in the last decade. As yet I must agree with the author that no definite agent has been produced that is of proved value in active immunization. As to passive immunization, the use of convalescent serum is of special interest. Since it is known that many, or the majority of cases of poliomyelitis are of the nonparalytic type, it would seem to me that its value, if any, would be in the preparalytic state, and how is it possible, except in severe epidemics, to make a definite diagnosis of this stage of this disease? Yet, even in those cases in which serum was used and thought to be of value, its therapeutic results have been questioned by many observers. The problems of immunity in poliomyelitis would be made easier if the exact portal of entry of this virus could be established. The author has again attempted to confirm his theory of the gastro-intestinal entry and he has attempted by experimentation of the use or nonuse of certain vitamins to reaffirm his ideas. Flexner recently again reviewed this subject fully and as yet disagrees with the author as to the theory of the introduction of the virus by the gastro-intestinal tract. Unless this matter is settled fully, some solution of the problem of immunity in poliomyelitis must be awaited.

DR JOHN FITCH LANDON, New York. In support of Dr Toomey's theory concerning the gastro-intestinal portal of entry, it is interesting that Dr L. W. Smith, pathologist at the Willard Parker Hospital during the large 1931 New York City epidemic, examined fifty-six olfactory bulbs from human subjects and found surprisingly little microscopic change in them. Students at the Rockefeller Institute working with monkeys have also recently been impressed by this observation.

The author's conclusions concerning the value, and in particular the safety, of prophylactic vaccines are sound. Sufficient data have accumulated to justify his stand that the advisability of employing prophylactic vaccines is very questionable. Interesting are the observations on the relative susceptibility of monkeys in which rickets is produced. However, from a clinical point of view it should be noted that children contracting poliomyelitis usually appear to have been in robust health with little evidence of rickets. The advisability of further trial of convalescent serum in massive doses is obviously a debatable question. Statistical analyses of large groups of cases treated with convalescent serum have in my opinion definitely proved that it is extremely doubtful. It is conceivable that the intravenous employment of serum might do some harm, since the intravenous use of any substance is always attended with some danger. In a fairly large series of cases at the Willard Parker Hospital, general reactions occurred in 18 per cent of the cases in which serum was administered by the intravenous route. The so-called preparalytic or nonparalytic cases show a low mortality and a low incidence of paralysis, so that the efficacy of serum treatment is extremely difficult to evaluate. At the Willard Parker Hospital, where no serum of any type has been employed since the epidemic of 1931, it is interesting to note that in 1932, 1933 and 1934 there were thirty-seven preparalytic cases with five deaths, while in 1935 there were 307 such cases with only two deaths. If we had become discouraged over our relatively poor results in 1932, 1933 and 1934, and had used serum in 1935, it is obvious what conclusions would have been drawn. Although there is no incontrovertible evidence that the intravenous use of serum may be harmful, to those of us who believe that the brunt of evidence is against it and that in the uncertain state of knowledge concerning the disease the foundation stone of therapy still remains complete rest, it seems reasonable to conclude that any disturbance of a patient who is apprehensive and hyperesthetic is a distinctly questionable procedure.

DR PAUL H. HARMON, Chicago. I believe that too many deductions have been made by applying the results of experimentation on monkeys to the human disease. The simplest experiment that would be readily applied to the disease in man would be an attempt to isolate the virus from the intestinal tract. We did a series of these experiments last summer in Chicago. Of twenty such patients, we were unable to isolate the virus in a single instance from the nasopharynx, but were able to obtain it in five instances from the gastro-intestinal tract. It will be argued by some that such an isolation of virus from the gastro-intestinal tract represents virus that has been swallowed. We were able in nine cases to examine olfactory bulbs from fatal cases from that epidemic. Lesions were absent in every case in those olfactory bulbs. All such evidence points to the gastro-intestinal tract as the probable portal of entry of the virus. Another thing that has not been taken into serious consideration so far is the question of strains of virus. We were finally able to establish one such strain in monkeys. It appears that this strain is immunologically distinct from the PMV strain that has so far been used in many laboratory investigations. Animals that recover from the 1936 strain are all susceptible to the PMV strain. That has been the experience of others with local virus strains recently. Trask, in a recent article, has been able to show that there are at least three or four such strains, a situation quite comparable to that of encephalitis in which there is the Japanese type, the St. Louis type and the von Economo type. With regard to the question of vitamins, clinical observations in connection with persons who are susceptible to this disease would argue that lack of vitamins does not predispose to susceptibility to this disease as those who contract the disease most readily are those who seem to be in most robust health. Certainly there is no deficiency of vitamin D in children toward the end of summer or in early fall. The use of serum in this disease has been argued for many years. Apparently we are getting no further with this argument than we were five or ten years ago. I might call to mind the experiences of Schultz and Gebhardt who showed that serum used prophylactically in the severe disease of monkeys cut down the incidence of the disease from 93 per cent to 70 per cent. I might also recall the experience of Levinson in the last four or five year period

in Chicago in which a negligible amount of paralysis was observed in preparalytic cases treated with serum. I believe without a doubt, that serum has a beneficial effect in this disease when used under the proper indications.

DR WILLIAM H. PARK, New York. I think that many know the results obtained by Drs. Aycock and Kramer in the New York 1936 epidemic. In a hospital in Brooklyn every enteric patient was carefully examined, and the exact amount of preliminary symptoms noted. Every alternate patient, taken regularly in order, was given the serum. At the end of the epidemic, both Dr. Aycock and Dr. Kramer reported their experience in an article showing that there were more serious symptoms and, at the end, more slight paralyses in those who had had the serum than in those who had not, and that there was one more death in the group that had had the serum. In the city as a whole, I arranged that we did not give the serum in hospitals. When we calculated the difference between the hospital cases and the outside cases, we found that there was practically no difference except that those getting the serum had, on the average, a little greater paralysis.

DR SIDNEY DAVID KRAMER, Brooklyn. Most physicians feel that the virus of poliomyelitis has its entrance to the body through the upper respiratory tract for the following reasons: 1. In spite of the major difficulties in obtaining a take in the experimental animal from human material, the virus of poliomyelitis has been recovered from the upper respiratory tract sufficiently often to be significant. 2. Efforts to recover the virus from the gastro-intestinal tract under normal conditions have been rather consistently negative, with the exception of the unpublished results just quoted by Dr. Harmon. Dr. Harmon is to be congratulated. Clark and Flexner and Scherp, although employing concentration methods, were unable to recover the virus from the intestinal contents of human beings and animals dying of the disease. 3. Infection of the experimental animal is relatively easily accomplished by the introduction of the virus into the nose, and this contrasts strikingly with the difficulties encountered in obtaining takes when the virus is introduced into the gastro-intestinal tract. Dr. Toomey's success in obtaining takes through the gastro-intestinal tract might readily be explained by the drastic measures he employs. 4. The epidemiology of poliomyelitis is that of a contact disease, like measles and diphtheria, in which it has been shown that etiologic agents enter the body through the upper respiratory tract. Dr. Park has just discussed the experiment conducted by the Academy of Medicine to determine the value of convalescent serum in the treatment of the disease. The results of this large experiment confirmed our own smaller alternate treatment experiment in Brooklyn and Hartford the same year (1931). Our results indicated that those patients who did not receive serum did quite as well as those who did. The same general impression prevails concerning the value of convalescent serum as a prophylactic measure. There is little or no evidence to indicate that human convalescent serum has any prophylactic value, and this in spite of the painstaking experiments of Brebner and Stokes. However, in view of the claims of McNamara and Levinson, were an unlimited amount of potent immune serum made available, it might be worth while reviewing the problem of the therapeutic and prophylactic value of such serum, using much larger doses than have heretofore been employed.

DR JOHN A. TOOMEY, Cleveland. Dr. Landon brings up the question of rickets as a predisposing factor in poliomyelitis. I should have been more clear about this point. Flexner objected to our experiments because of the drastic methods employed to introduce the virus into the gastro-intestinal tract. I wished to put the animal in such a state that its gastro-intestinal tract would absorb virus immediately without using the drastic methods objected to. I found that if I produced rickets in the monkey I did not need to resort to drastic measures to produce the disease. I could not state that rickets proved to be one of the predisposing factors in human poliomyelitis. To one who has always believed that the gastro-intestinal tract was the portal of entry in this disease Dr. Harmon's remarks are encouraging indeed. Dr. Kramer states that poliomyelitis is a contact disease. Why then don't monkeys exposed to other monkeys with the disease contract the infection?

IMPORTANCE OF THE ADEQUATE
TREATMENT OF FRACTURES
IN RURAL HOSPITALS

WILLIAM T HAMMOND, M D

EASTON, MD

An accurate statement as to the exact number of fractures treated annually in the United States is virtually impossible. Estimates vary from 1,000,000 to 1,500,000. Of these a large proportion are treated in hospitals. The American Medical Association has registered 2,900 small general hospitals, many in country districts that each year admit and treat thousands of fracture patients.

When the fracture patients constitute a considerable proportion of the total number of admissions, as in industrial centers, there is generally sufficient equipment and trained personnel present to insure adequate treatment, but in some of the smaller places, where comparatively few fractures are seen, facilities for prompt and efficient care are not always available. Yet statistics of casualty insurance companies show that about two thirds of all major automobile accidents occur in rural sections, demonstrating that our high speed machine age accounts for an increasing number of fractures in country hospitals regardless of our capacity to care for them properly. Many such victims of motor car accidents are strangers, hurt far from home, and hence they have no choice in the selection of a physician. Thus the responsibility for their treatment is entirely on the institution to which they are admitted.

I have visited a number of small hospitals in the past year and made some investigation of fracture treatment. An appalling lack of interest is found in many places, every one with hospital privileges treating fractures of all types, except possibly fractures of the skull, which are referred to the surgeon. Also there seems to exist a belief that any doctor can set a broken bone or, if any attempt is made to segregate fracture work, it is turned over to the youngest and most inexperienced staff member because the tedious and time-consuming attention to detail required over a period of weeks makes such work unattractive to the busy surgeon as well as beneath his dignity in too many instances.

Analysis of a long series of cases in one of the larger hospitals showed that a considerable percentage of the patients admitted for open reduction, onlay, inlay or bone plating were referred from small hospitals, where there was no one sufficiently experienced to attempt such operations. Evidently such cases were treated by men who were not trained in fracture treatment, since a study of the history and x-ray films made obvious the fact that proper early reduction and immobilization would have made operation unnecessary in many instances.

It is true that small communities cannot support a properly trained orthopedic surgeon to supervise the fracture department, yet the need for skilful handling of severe fractures is nevertheless constantly present. Most of the patients who need special care cannot be transported to the larger institutions for treatment because of the elements of expense, time and condition of shock. That many of these small institutions, how-

ever, are in contact with orthopedic surgeons who understand the principles of fracture therapy, some who visit such hospitals as consultants can testify. The situation, then, is about as follows.

There are many small hospitals located in the field of action, with a special group of patients, who, because of the emergency nature of their cases cannot well be moved but who are in need of prompt treatment. At the same time, scattered over the country in the larger hospitals, are experienced orthopedists willing to give assistance. Isn't it only logical to attempt some means of combining forces toward providing sufficiently skilful treatment to give fracture cases the best possible chance for satisfactory results with a minimum of time and expense? I shall try to present here the point of view of one who has wrestled with the fracture problem in a small town, of one familiar with the difficulties in an isolated country hospital. It is the story of how we worked out a solution, a compromise, if you will, but one which keeps our patients in the local hospital, yet gives them the benefit of the experience of an orthopedic surgeon in a nearby city.

For twenty-five years I have been on the staff of one of these country hospitals and for the past fifteen years I have conducted a fracture clinic. The place in question, the Emergency Hospital at Easton, Md., is a fair example of an average country hospital. It is small, of seventy bed capacity, staffed by local physicians. It is situated in an agricultural community without large industries, and it admits annually a small number of fracture patients.

At first thought one would not consider our fracture problem an important one because of the few cases treated. This fact for a long time dulled our sense of responsibility to fracture patients, and it was not until our attention was called to some of the unsatisfactory results that we realized our shortcomings. In our hospital, as in most other institutions of its type, for many years the treatment of fractures was not given special consideration. Each man treated fractures occurring in his practice with no one else paying much attention to them, and it was simply taken for granted that any one who sustained a major fracture was destined to carry some deformity or disability for the rest of his life.

Seventeen years ago our hospital, with the cooperation of the Rotary Club, asked Dr. Robert W. Johnson to conduct a monthly clinic for crippled children. He did so, but for the first two years much of his time was unavoidably diverted from the clinic and spent in the operating room, where he opened and plated many ununited and imperfectly reduced fractures. Finally, he suggested to the staff that our handling of fractures could be improved, and he discussed with us the advisability of appointing one staff member for fracture service, as no one man treated sufficient fractures to stimulate a keen enough interest in the work. It was hoped that with only one individual in charge he would inevitably be interested in his department and that he would visit other clinics and keep himself informed as to the new and approved methods for handling fracture patients. In conjunction the other staff members agreed to refer their fracture cases to the new department and to allow the chief full responsibility for their care. We then went ahead.

The necessary equipment of Balkan frames, traction devices, fracture table and bedside x-ray equipment was procured through the generosity of friends. A room

near the receiving ward was set aside for a fracture room, and Dr. Johnson promised to stand by with advice and assistance whenever necessary.

In the early days of our clinic this advice was eagerly sought. Our consultant was frequently called on the telephone, x-ray films were hurriedly dried and sent him for an opinion. Often he would come across Chesapeake Bay, in all kinds of weather, to advise and help in the management of some difficult case, generally without compensation. Evidently he had faith in the project he had encouraged and was willing to make any sacrifice to insure its success. As a consequence we believed in it, too.

When first established, the fracture service had no official status as a hospital department. It was operated entirely through mutual agreement among the members of the staff. But this informal arrangement placed the burden of proof on the chief of the service and stimulated him to prove the value of the innovation. After some years, during which time the clinic continued to grow and receive the support of physicians in the surrounding territory, it was given the official title of "Fracture Service," and all fracture patients were admitted directly to this department.

Except for automobile accidents, which at present account for 20 per cent of our cases, there is no one factor largely responsible for the manner in which fractures are sustained. They are simply the result of the manifold usual accidents of civil life—falls down stairs or on the street, farm accidents, playground injuries, and so on, but we admit about 200 fracture patients a year.

Before the establishment of the service, most of the elderly patients who had sustained a fracture of the hip were kept at home, as hospitalization then offered little improvement over the treatment given by the family doctor. When these patients were referred to the fracture clinic, our first method of treatment that offered any reasonable hope of union and function was the Whitman spica cast. Satisfactory results were obtained in about 40 per cent, which was disappointing when one considers the length of time the cast is worn and the nursing care employed. The announcement of a simplified technic for the use of the Smith-Petersen nail was received by us with enthusiasm. It is now used almost as a routine. When accurately placed, with the fragments impacted, it has proved to be the most satisfactory treatment we have used. While it is too early accurately to state the percentage of good results, it will far exceed our previous figures. Taking these hip fracture patients out of bed and putting them on crutches in a comparatively short time is a life-saving procedure for a group who find immobilization in a cast almost unbearable. For the same reasons, some type of well leg splint is used in the intertrochanteric fracture. It provides sufficient traction, and the patients enjoy the freedom of a wheel chair much earlier than in other methods we have employed.

In the treatment of fracture of the shaft of the femur we have watched the evolution of traction from Bucks extension to bone calipers, from Kirschner wire to Steinman pin, and in turn have used all of them. At present, when feasible, we are using skeletal fixation with steel pins combined with a plaster cast. Patients treated in this manner are apparently quite comfortable, there is little likelihood of displacement; they require a minimum of nursing care as compared with the suspension and traction method; and their period of hospital-

ization is materially shortened. That is an important item in an institution of limited bed capacity.

While there has been considerable criticism of the promiscuous use of Steinman pin fixation by untrained persons, this technic has given us excellent results in cases of severe comminution and spiral oblique fractures of both bones of the lower leg. The method is not used when fractures can be reduced and held in position in a cast, but when we must choose between a probable gross deformity and the insertion of pins, our choice is the latter.

Seventy-five per cent of the fractures of the humerus have required some type of traction, either ambulatory or with suspension. All our cases with fracture dislocation of the head of the humerus required open reduction, and in most instances resection of the head.

In one group we have a definite routine. I am referring to fractures of the elbow in children. These are all reduced under general anesthesia. After manipulation and reduction, we make anteroposterior and lateral x-ray films before any splint is applied. When the film shows satisfactory reduction, a posterior plaster splint is applied leaving the inner aspect of the elbow exposed. The patient is then required to stay in the hospital at least twenty-four hours for observation.

Fractures of the shaft of both bones of the forearm in adults have been difficult to handle. Various types of traction splints have been tried with indifferent results. Open reduction, when resorted to, has not always been satisfactory. Our best results have been obtained through the use of a half pin in the radius and a pin through the ulna near the olecranon. As a rule, good reduction can thus be secured, and by incorporating the pins in a cast, held until union is complete.

It is only natural that I should experience some embarrassment in presenting this paper before the Section on Orthopedic Surgery. I am not an orthopedist, and before the establishment of our clinic I had no training in fracture treatment. It should therefore be remembered that when I elaborate on the methods used in our hospital it is only for the purpose of showing the general scope of the work and not intended as a treatise on the proper methods of treating fractures.

After observing the good results secured in other clinics, we adopted some of the mechanical devices that utilize pins and wires for skeletal fixation. While their use does entail some hazard, proper selection of cases and a scrupulously careful technic will eliminate most of the dangers. We do not believe, however, that machine shop precision and modern gadgets can replace careful individual attention to reduction, immobilization, frequent observation and follow-up service. To conduct such a service in a small place means hard work and long hours, but there is no other branch of medicine or surgery in which the drudgery of detail is better invested than in the treatment of fractures.

Most of our patients are received in a comparatively short time after injury and we are able to do early reductions. On admission, the patient, unless a condition of shock makes it unwise, is placed on the fracture table, roentgenograms are made, and a plan of treatment is decided on.

All patients are given a physical examination and a routine Wassermann test, and the facilities of the hospital are available as for any other patient. The fracture chart, as approved by the American College of Surgeons, is used as a routine. Serial x-ray studies

are also made when necessary. After reduction, all fractures are roentgenographed in two positions or stereoscopically.

Considerable time will be saved if the fracture chief can interpret his x-ray films and has a knowledge of the proper positioning of patients. Our fracture room has its own x-ray unit, a shock proof bedside machine which is used for fluoroscopic control of reductions, for taking films of most fractures of the extremities and for general bedside work in the wards. We are in most instances independent of the regular x-ray laboratory and thus avoid unnecessary moving of the patients.

The responsibility for improving the treatment of fractures in the small hospitals of the country rests more heavily on the orthopedic surgeons of America than on any other group. More can be accomplished by the individual guidance and assistance of orthopedic surgeons than by fracture committees and hospital surveys although I do not minimize the importance of these organizations when and if they function. But orthopedic surgeons are recognized as authorities on this subject and their opinions are respected by the rural hospital staff and the physicians who refer patients to them. Not only will their advice be valuable to any clinic but their endorsement will ensure for it the recognition necessary for successful operation. In the small hospitals which have met the minimum requirements of the American College of Surgeons, fracture treatment has only recently been given serious consideration. The rules of such hospitals require that most surgery be performed only by those who have been properly trained, yet there is nothing to prevent any one from treating severe fractures. At present the fracture committee is attempting to develop suggestions and regulations for fracture treatment and give this work the recognition it deserves.

One of the most important items in the building up of a fracture service is the cooperation of the hospital staff in referring patients to the clinic. In our hospital we have been fortunate in that most of our colleagues demonstrated a high type of cooperative spirit and willingly relinquished their patients to the fracture department. In this connection the orthopedic consultant can play an important role, he can freely discuss this matter of referring patients and request the support of the staff for the new department, all of which would be difficult and possibly embarrassing for the fracture chief to do for himself.

We have made no appreciable progress in improving the transportation of fracture patients. Ambulances equipped with Thomas splints are not always available. As a rule patients are placed in the first car to reach the scene of the accident and rushed to the hospital. Frequently they are received in a state of shock as a result of the rough handling and the ride.

The best examples of emergency splinting seen by us were contributed by Boy Scouts and telephone crews, who used whatever was available for splinting. Patients given first aid by them arrived at the hospital in good condition. Within another generation the full benefits of the first aid instruction given to the youth of today should be manifest and more intelligent roadside care will be rendered the injured.

SUMMARY

1 As two thirds of all major automobile accidents occur in rural districts, it is necessary that the small hospital treat an increasing number of fracture patients. Present methods are unsatisfactory in many places.

2 Better care of these patients can be provided by a definite fracture service or clinic.

3 The necessary equipment need not be elaborate or expensive and is well within the financial limits of most small institutions.

4 An orthopedic consultant can help materially in building up such clinics because of his acknowledged position of leadership in fracture work.

CONCLUSION

I suggest that orthopedic surgeons use their influence, offer encouragement to the small hospitals and aid them in establishing a fracture service wherever interest is shown.

The successful operation of our fracture clinic for the past fifteen years under the supervision of an orthopedic consultant, but directed by the local chief of the service, proves the practicability of the plan, and it seems probable that the same general scheme must be applicable to many other small hospitals throughout the country.

208 Goldsborough Street

ABSTRACT OF DISCUSSION

DR GEORGE E BENNETT, Baltimore. This represents an ideal set up, which should furnish an example for all orthopedic surgeons. I have had the opportunity of hearing Dr Johnson discuss the development of this fracture clinic with Dr Hammond. It shows what can be done with a very unusual general practitioner who is properly guided and instructed and who has working at his side an enthusiastic orthopedic surgeon who is willing to give the time and the labor to see that he is properly instructed. The development of key men of Dr Hammond's type in small hospitals throughout the United States is one of the matters in which this organization and other orthopedic organizations must become interested. I know of no single unit in a small rural hospital where there has been such a change in the end results of fractures as there has been in this small hospital in Easton, Md. Prior to the development of this unit the hospitals in Baltimore were constantly receiving very badly handled fracture cases from the entire eastern shore of Maryland and now we seldom see one. Dr Hammond is to be congratulated and encouraged, and I hope that every one will be able to make as good a choice in a country practitioner as Dr Johnson in his selection of Dr Hammond as his co-worker.

DR VOIGT MOONEY, Pittsburgh. Dr Hammond's attempt is not always true in the rural hospitals. It is difficult to take up all the phases of Dr Hammond's paper, so I shall show a few lantern slides which will graphically express some of my views on the handling of fractures in rural hospitals. I may state that I am opposed to the open treatment of fractures, especially in children.

Tuberculosis in Children.—At one time it was thought that the first infection type of tuberculosis is established in a high percentage of children before the period of adolescence. This probably was true in many places and apparently is still true in a few densely populated centers, such as Philadelphia. However throughout the greater part of the United States and in some other parts of the world the campaign against tuberculosis in man and animals has so greatly reduced or controlled the number of cases of communicable tuberculosis in both man and animals that large numbers of children now grow to adult life without having had the first infection type of tuberculosis. Indeed, in a few places the situation has been so completely reversed that although formerly from 90 to 95 per cent of the young adults had been infected now only from 5 to 10 per cent react positively to the tuberculin test—Myers, J. A., Diehl H. S., Boynton Ruth E. and Trach, Benedict. Development of Tuberculosis in Adult Life. *Arch. Int. Med.* 59:1 (Jan) 1937.

BENIGN LYMPHOCYTIC CHORIO-
MENINGITISLABORATORY STUDIES WITH THE VIRUS AND
THEIR POSSIBLE BEARING ON THE
INFECTION IN MAN

CHARLES ARMSTRONG, M.D.

AND

JERALD G. WOOLEY, M.D.

Senior Surgeon and Bacteriologist, Respectively United States
Public Health Service

WASHINGTON, D. C.

The virus of benign lymphocytic choriomeningitis was first isolated and described by workers at the National Institute of Health in 1934¹ Traub² at Princeton in 1935 and Lepine and Sautter³ at Paris in 1936 recovered similar strains of virus from white mice, and Rivers and Scott⁴ at New York in 1935 and also Findlay, Alcock and Stern⁵ at London in 1936 isolated strains from human beings with nervous manifestations.

These various strains affected animals in a similar manner and have been shown to be immunologically similar to the original strain isolated by Armstrong¹. The virus is pathogenic for monkeys, guinea-pigs, mice and white rats and is capable of affecting many tissues and organs. For instance, Armstrong, Wooley and Onstott⁶ demonstrated an abundance of the virus in the brain, lungs, kidneys, heart muscle, voluntary muscles, marrow, salivary glands, adrenals, spleen, liver, testicles and blood of infected monkeys. Lillie,⁷ moreover, demonstrated that the presence of the virus in the various organs was accompanied by micropathologic changes.

The symptoms in experimentally inoculated monkeys differ in severity depending on the dose, the strain of virus and the route of inoculation. When inoculated directly into the central nervous system, the virus produces well marked symptoms and often death in monkeys and is usually fatal to mice and guinea-pigs. When it is introduced otherwise than directly into the central nervous system, it is extremely rare according to our experience for symptoms suggesting involvement of the central nervous system to ensue, and this is true even though the inoculation follows local irritation produced by the injection of foreign material into the brain. Monkeys so inoculated may be febrile for a few days, not eat well and appear somewhat ill. However, an afebrile, asymptomatic type of infection with virus demonstrable in the circulating blood has been noted.⁸ Monkeys and mice have been shown also to become immune to intracerebral inoculation after subcutaneous injection of the virus even in the absence of symptoms detectable by usual observations. Moreover, the serum of immune monkeys, as demonstrated by Armstrong and Wooley⁹ and others,¹⁰ when mixed with the virus

in proper proportion is capable of neutralizing the latter, as is shown when the mixture is injected intracerebrally into normal animals.

NEUTRALIZING ANTIBODIES IN THE SERUM
OF MONKEYS

We have demonstrated potent antibodies¹¹ in the serums of sixteen of seventeen monkeys which had been well for various intervals after recovering from an experimental infection with the virus of choriomeningitis, while of eight noninoculated monkeys, sixteen that had received the virus of poliomyelitis and eleven that had been inoculated with the virus of encephalitis (St. Louis type) all had negative reactions except two. The two exceptions had both been for some time either in direct or indirect contact with infected animals. Moreover, one spontaneously infected monkey was actually observed,⁹ hence, the serum virus protection test appears to afford a means of detecting the presence of specific antibodies in the serum of monkeys.

CHORIOMENINGITIS VIRUS AS A CAUSE OF
DISEASE IN MAN

Two strains of a previously undescribed virus were isolated at the National Institute of Health during studies of autopsy material from two cases. One subject had died of encephalitis, St. Louis type, and the other apparently of a staphylococcal invasion of the brain. We could not, however, be certain that the viruses had not been picked up from our transfer animals (monkeys). The similarity of the symptoms and the changes in the spinal fluid in monkeys to those recorded in cases of "aseptic meningitis" in man was, however, pointed out by Armstrong,¹ who later, with Wooley, demonstrated the presence of specific neutralizing antibodies for the virus in the serum of persons who had recovered.

Armstrong and Dickens¹⁰ noted the absence of such antibodies from the serum taken early in the course of an attack of "aseptic meningitis" and their development during convalescence. Rivers and Scott⁴ and Findlay, Alcock and Stern,⁵ moreover, have isolated strains of the virus from human beings with this clinical entity, so that the etiologic rôle of the virus in certain clinical cases of "aseptic meningitis" is established.

PROTECTIVE ANTIBODIES IN HUMAN SERUM

Workers at the National Institute of Health have completed the testing of 1,248 human serums for the presence of antibodies capable of neutralizing the virus of lymphocytic choriomeningitis, 138, or 11 per cent gave definitely positive results. Fifty-eight of the 1,248 serums were from persons whose condition was clinically diagnosed as "aseptic meningitis", in nineteen, or 32 per cent, neutralizing antibodies against the virus isolated at the National Institute of Health were demonstrated.

In some instances the serums were collected too early in the attack for one to have expected the presence of specific antibodies, and it was not possible to secure later samples. There were, however, numerous cases in which the condition was considered to be clinically "aseptic meningitis" in which the results of the protection tests were negative with serum collected well after convalescence and even with repeated samples of serum. Such results might be explained by immunologic differences in strains such as have been observed in the case of certain other ailments due to viruses. However, the

strains of virus already isolated from widely separated regions have all been immunologically similar. Moreover, the fact that we failed in several instances to isolate the virus from material collected at a time when its presence should have been expected is against this interpretation. We have been led, therefore, to feel that the clinical entity "aseptic meningitis" is made up of more than one etiologic entity. The serum virus protection test indicates that approximately one third at least of the fifty-eight cases of "aseptic meningitis" investigated were probably caused by the virus under discussion, for which cases we have therefore suggested the specific designation of benign lymphocytic choriomeningitis. The cases in which protective antibodies for the choriomeningitis virus were not demonstrated were cases of such diseases as tuberculous meningitis, poliomyelitis, encephalitis of the lethargic, St. Louis or postinfection type, or of other ailments of the central nervous system, of unknown cause.

It is to be noted, however, that protective antibodies in the serum were much more frequently observed (11 per cent) than was a history of aseptic meningitis. Many persons with antibodies were carefully questioned by Dr. Wooley and denied a history of any disturbance of the central nervous system whatever. Obviously, then, either the protection test as carried out is not specific for choriomeningitis or the antibodies are the result of a nonrecognized type of infection with the virus.

Careful interrogation of many persons showing antibodies and having no history of any ailment of the central nervous system was made by Dr. Wooley and revealed infections of the upper part of the respiratory tract designated as "grip," "influenza" or "colds" as the only diseases common to the groups.¹² It may therefore be of some significance that of 106 serums from persons with rather recent infections of the upper part of the respiratory tract, thirty, or 28.3 per cent, showed definite protection, an incidence second only to that shown in cases of aseptic meningitis (32 per cent). In this connection it is of interest to note that several proved cases of choriomeningitis began with symptoms of grip or head cold, to be followed a few days later by meningeal symptoms. In view of the fact that the choriomeningitis virus attacks many tissues in animals, these premonitory symptoms in man suggest a systemic type of infection which, as suggested by the history and protection test results, may only exceptionally be followed by involvement of the central nervous system.¹³

AGE INCIDENCE

As already noted, the serum of 11 per cent of the 1,248 subjects gave definitely positive results in the serum virus protection test, 486 of these subjects were known to be over 16, and of these ninety, or 18.7 per cent, showed positive protection while of 345 normal persons 16 or under who lived in orphanages or training schools in Maryland, Virginia or South Carolina and fifty-one ill children from various localities (a total of 396) not one showed strong protection and but five, i. e., 1.2 per cent, a moderate degree of protection. It might also be pointed out that the small number of attacks proved to be due to the choriomeningitis virus all occurred in persons over 20.

This relative infrequency of serologic evidence of infection by the virus of choriomeningitis in children as

compared to that in adults is unexplained, but several possibilities suggest themselves.

1 The adult and child groups in our series may not be representative samples of the general population.

2 Possibly the virus was epidemic about 1921, after which it tended to disappear until recently. This explanation could hold only in case the neutralizing antibodies tend to persist for years after the attack. Evidence on this point is meager, but Armstrong and Dickens¹⁰ reported the persistence of antibodies for three years and eleven months after the supposed attack. Serum collected from the same patient after four years and seven months showed no detectable diminution of antibody content.

3 It is conceivable that immunity in children, like that in mice, is not accompanied by the development of humoral antibodies.

4 Children conceivably may be resistant to infection, lack exposure or both.

METHOD OF SPREAD OF THE VIRUS

We have found it possible to transmit occasional infection in monkeys by intra-urethral and intravaginal instillations.⁶ These observations, together with the fact that we have demonstrated the virus in the urine of infected animals, where it tends to persist, as well as in the testicles and seminal vesicle fluid of infected animals, and the higher incidence of antibodies in man following puberty, at least suggest the possibility that a venereal transmission may constitute one route of infection in this disease. In this connection, it is of interest to note that 3.9 per cent and 1.3 per cent, respectively, of the serums of fifty-one adults in the St. Elizabeths Hospital for the insane and seventy-one sufferers from the St. Louis type of encephalitis in various localities, many of whom were adults, gave positive results with the serum virus protection test, as compared to an incidence of 17 per cent and 19.7 per cent, respectively, of positive protection for serums from 275 inmates of federal penitentiaries and 314 patients at the Marine Hospital. That convicted criminals constitute a group highly exposed to venereal infection is indicated by the fact that the Wassermann reaction was positive in sixty-two, or 22.5 per cent, of the 275 serums submitted to the serum protection test. It is, moreover, known that certain of the serums with a negative Wassermann reaction had been rendered so by vigorous antisyphilitic treatment.

The evidence suggesting a venereal route of infection is, to be sure, in no sense conclusive and is mentioned merely as one possible route of infection to be kept in mind by persons who may have an opportunity to investigate cases of benign lymphocytic choriomeningitis.

The serums submitted to the protection test were largely from male patients, so that it is not possible to make any comparison of the occurrence of antibodies in the serums of the two sexes. A more detailed analysis of our results with the protection test on 1,248 serums will appear shortly in *Public Health Reports*, to which those interested may refer.

CONCLUSIONS

The virus of benign lymphocytic choriomeningitis first described in 1934 has been recovered from man and from animals in several localities of the United States, in England and in France, and the demonstration of antibodies in 11 per cent of 1,248 serums from scattered areas of the United States by the serum virus mouse protection test, which we believe to be specific, indicates that this virus may be of greater importance

¹² Two of the e were laboratory workers at the National Institute of Health whose attendance records could be checked and who had had no recent illnesses other than occasional headaches and grip.

¹³ The histopathology of choriomeningitis in man is unknown since there have been no deaths in proved cases.

as a cause of human infection than the occasional cases of involvement of the central nervous system would indicate

ABSTRACT OF DISCUSSION

DR PAUL DICKENS, Washington, D. C. The authors report a new disease entity, benign lymphocytic choriomeningitis, and separate it from a group of diseases previously designated "aseptic or benign lymphocytic meningitis." The workers of the National Institute of Health and in particular Dr. Armstrong should be given the credit for first isolating and reporting the virus of this disease. The incidence of benign lymphocytic choriomeningitis is not as uncommon as previously supposed if the authors' figures on random sampling of blood serums showing 11 per cent or more positives is taken as a criterion of its prevalence. By analogy this would also indicate that the diagnosis is being all too frequently missed. From an immunologic standpoint there seems to be no doubt that the virus isolated by Armstrong is the etiologic agent in benign lymphocytic choriomeningitis. In a series of cases reported by Armstrong and Dickens, it was noted that during the first two weeks of the disease the serum virus mouse protection test was negative but early in the third week became positive. This fact is important, as the authors state that the diagnosis in certain cases has not been determined, owing to the taking of blood serum for the mouse protection test too early in the course of the disease. It is good practice, however, when one is able to do so, to take the serum early and, if it is negative, to repeat the test after the third week. Should the test then be positive it would be immunologic proof of the disease. I wish to emphasize the fact that there is an almost pure lymphocytic cellular response in the spinal fluid. It was noted that the mouse protection test was positive only in cases in which the cerebrospinal fluid contained 90 per cent or more of lymphocytes, while in the cases in which there was an increase in polymorphonuclear cells as well as in lymphocytes, even though the lymphocytes were above 50 per cent, the test was uniformly negative. I mention this in view of the varied cell count of the cerebrospinal fluid given in the literature on aseptic lymphocytic meningitis, and Dr. Armstrong's statement that numerous patients considered clinically aseptic meningitis gave negative protection tests. The suggestion of Dr. Armstrong that there may be a systemic invasion of the disease without metastases to the central nervous system is interesting. May I ask whether these missed cases may not be considered a source of spread of the disease? All my patients found by Dr. Armstrong to give positive serum-virus mouse protection tests had an initial infection of the upper respiratory tract followed later by symptoms of meningeal irritation sufficient to warrant a spinal puncture. The authors' figures of 28.3 per cent positive in 106 cases of recent infection of the upper respiratory tract is significant and warrants further study. When a new disease first appears in a community the attack rate is highest in the upper age group (the St. Louis epidemic of encephalitis), the succeeding waves attacking the younger group. This may be one reason for the low incidence of the disease in children in this country.

DR JOSEPHINE B. NEAL, New York. I have never seen a case of benign lymphocytic choriomeningitis. I have tried to make the diagnosis but up to the present time have not been able to demonstrate the virus or the antibodies. In consequence I have quite an unprejudiced point of view. Those of us who are working with acute infections of the central nervous system feel that the further we go—I don't like to say the less we know, but rather the more we find that we would like to know. In the literature there has been a tendency to diagnose "benign lymphocytic meningitis" or "benign lymphocytic choriomeningitis" without adequate laboratory confirmation. I agree with both Dr. Armstrong and Dr. Dickens that the diagnosis must be established by the demonstration of the virus or of the antibodies in the convalescent serum. After studying descriptions of these cases I have wondered whether the title "benign lymphocytic choriomeningitis" adequately describes the disease in man. In two cases reported by Findlay and his associates, for instance, there were extensive sensory disturbances and considerable paralysis and one patient of Dr. Viets had some

paralysis that was more temporary in nature. It seems to me that those symptoms indicate a parenchymal involvement which the term "meningitis" does not describe. Moreover, I do not believe that it is possible for us to pass directly from the pathology of the experimental disease in animals, in which it is, I believe, a simple meningitis, to the pathologic condition found when some patient has died during an attack of this disease and a complete histopathologic study has been done on his brain.

DR HENRY R. VIETS, Boston. Some light is gradually accumulating on this syndrome or this disease, if we want to call it such. Thanks to Dr. Armstrong a virus has been found which causes a condition in animals very similar, if not entirely similar, to that which has been seen in man. The history of the disease is of some interest, because Wallgren in 1925 described aseptic lymphocytic meningitis in children, and his work was not accepted generally at the time in the neurologic literature. In this country, Viets and Watts saw their first patients in the fall of 1928 and published two papers in 1929 reporting five cases. Since then I have been interested in the clinical syndrome and have gradually accumulated a good many cases, all of which seem to fall into a group that justifies being classified as a separate disease. Dr. Armstrong has given us enough additional encouragement to call the syndrome a disease, and if we now can add some information from human cases ultimately we shall get a complete picture of this type of meningitis. The only case that has been brought to pathologic examination, so far as I know, is one which Viets and Warren reported in 1937. Unfortunately the patient died before Dr. Armstrong's announcement of the virus, so the patient's blood could not be tested by the method which would be used today, therefore the case must be considered as unproved. The patient, however, showed the clinical manifestations of the disease and the cerebrospinal fluid manifestations were such that we were satisfied with a diagnosis of acute lymphocytic meningitis. Although the disease is seldom fatal, it would seem likely that if one death occurred in the last few years there will be more. The test that should be done in all cases is to check with the virus of Dr. Armstrong or Dr. Rivers before the definite diagnosis is made clinically. This work of Dr. Armstrong is most important. It is not the first time neurologists have been helped by the National Institute of Health.

DR CHARLES ARMSTRONG, Washington, D. C. I am glad that Dr. Dickens and Dr. Viets have mentioned the clinical picture, because at the National Institute of Health we lack clinical material and I felt that it would be presumptuous on my part to discuss the clinical picture before men who have seen so much of it. As regards the questions which Dr. Dickens raises as to the virus spreading through missed cases, I think it is a likely probability. We have in none of these cases been able to trace a contact between known cases. If it is infectious, as we feel it must be, it is possibly through these missed cases or possibly carriers of diseases. Dr. Dickens thinks the respiratory route is a probability, and we certainly couldn't deny that. However, to say that because there is a respiratory symptom it necessarily means that the infection enters by that route is fallacious. We have inoculated the virus directly into the lung tissue and the resulting picture was just about what we got when we put it subcutaneously. A few of our monkeys did, however, develop a rather persistent cough, and there was no very apparent pathologic change to explain the presence of such a cough. So far as I know such a cough has not been recorded in the human cases proved to be due to this disease. As to the age incidence indicating this is a new disease, it may possibly point in that direction. I am not wedded to the name, and it is possible that future experience with this disease in man will indicate that we should at least throw off the "benign" and possibly add "encephalitis" but there is certainly in those human cases that have been proved to be due to this virus considerable variation in the symptomatology. Some cases have been relatively severe others have been very mild. As to the testing of serum, any one should encounter suspected cases we would be pleased if you would send us the serums. All you need to do is draw the blood sterily and send the whole blood without preservatives. We have found that a certain amount of hemolysis makes no difference with the test. We shall be very glad to test such serums.

USE OF PROSTIGMIN AS A DIAGNOSTIC TEST OF MYASTHENIA GRAVIS

GEORGE D GAMMON, M.D.
AND
HAROLD SCHEIE, M.D.
PHILADELPHIA

That prostigmin relieves the muscular weakness of myasthenia gravis has now been accepted quite generally by all observers who have studied the drug¹ This relief, furthermore, has provided new insight into the mechanisms at fault in the disease The possibility of using the response to prostigmin as a diagnostic test of myasthenia has not, however, been fully appreciated It is true that Viets and Schwab² have found that the weakness due to lesions of the central and peripheral nervous system was not materially improved However,

five cases of progressive muscular dystrophy, two cases of myotonic dystrophy, one case of family periodic paralysis, two cases of amyotonia congenita, five normal adults, and three normal children The patients were studied in the Neurological, Medical and Pediatric services of the University Hospital, diagnoses were made after careful study

In estimating changes in muscular contraction we observed facial movements and, wherever possible, we employed such objective tests as weight lifting, dynamometer tests and the height to which a mercury column could be blown In some cases myographic records were made

As a test dose from 1.5 to 2 mg of prostigmin hypodermically was used, combined with atropine sulfate $\frac{1}{100}$ grain (0.00065 Gm) It should be emphasized that a large dose is required to obtain the desired response Children tolerate about half the adult dose³

The effect of prostigmin on myasthenia gravis. The graph illustrates the height to which a column of mercury could be blown At 0 hours prostigmin 1.5 mg and atropine sulfate $\frac{1}{100}$ grain (0.00065 Gm) were given hypodermically Successive pictures were taken at the points marked by arrows In each the patient was attempting to smile

the effect of prostigmin on the muscular diseases has not been systematically studied We have accordingly examined the action of the drug on the weakness due to a variety of diseases of the muscular system None of the patients obtained any striking relief from prostigmin Therefore myasthenia gravis is the only condition examined thus far in which muscular weakness is consistently and markedly improved For this reason it seems fair to conclude that a response to prostigmin may be used as a diagnostic test of the disease

MATERIAL AND METHODS

The cases studied include four cases of myasthenia gravis, in one of which hyperthyroidism had developed,

EFFECTS OF PROSTIGMIN IN CASES OF MUSCULAR DISEASE AND MYASTHENIA AND IN NORMAL PERSONS

Prostigmin in doses ordinarily employed in the treatment of myasthenia sets up marked fibrillary tremors in the muscles of normal persons and in all these cases of muscular disease except myasthenia While best seen in the eyelids and tongue, the fibrillations occurred irregularly throughout the body and did not selectively affect the diseased muscle The twitching probably results from repetitive contraction of small groups of fibers in response to tonic impulses, since Brown, Dale and Feldberg⁴ have observed that muscle treated with physostigmine gives a multiple response to a single stimulus applied to the motor nerve In the muscular dystrophies the twitching was considerably more marked

Dr Gammon is Godey and Seeger Fellow From the Medical Clinic of the Hospital and the Institute of Neurology the University of Pennsylvania School of Medicine Supported by the Kirby McCarthy Fund

2 Viets H R and Schwab R S Prostigmin in the Diagnosis of Myasthenia Gravis New England J Med 212 1280 1283 (Dec. 26) 1935

3 The drug was furnished by Dr R D Shaner of the Hoffman LaRoche Company
4 Brown L Dale H H and Feldberg W Reactions of the Normal Mammalian Muscle to Acetylcholine and to Eserine J Physiol 87 394 425 (Sept) 1936

than in normal persons, indicating probably an increased sensitivity to the drug. In myasthenia gravis, in contrast to these cases, fibrillations almost never occurred, only rarely were they observed in the lids. The absence of a normal reaction suggests that the myasthenic process is generalized and widespread.

While the lack of fibrillary twitching distinguished myasthenia from the other cases examined, a much more striking difference was evident. For the weakness of myasthenia was consistently and spectacularly relieved, as shown in the illustration, but that of the other conditions was either not materially affected or, in some cases, was slightly increased. Thus only one of the seven patients with dystrophy obtained an increase in strength and this was so slight as to require careful measurement to demonstrate the change. The patient with periodic family paralysis was made somewhat weaker.

Thus, of the various muscular diseases that we examined, myasthenia gravis alone responded to prostigmin with significant increase in the strength of muscular contractions. Since, then, others have shown that weakness due to lesions in the central and peripheral nervous systems is also not materially improved by prostigmin, a marked improvement in muscular weakness by prostigmin and the absence of fibrillary tremors is a diagnostic test of myasthenia. In other words, prostigmin appears specific for myasthenic weakness, since it relieves no other condition so far examined. It is possible that prostigmin may find its widest usefulness as a test to differentiate myasthenia from other causes of muscular weakness.

XANTHOMA TUBEROSUM ASSOCIATED WITH TRAUMA AND MILD DIABETES MELLITUS

EUGENE S. SUGG, M.D.
AND
DUDLEY D. STETSON, M.D.
NEW YORK

In reporting this case illustrating the striking lesions of a rare skin disease—xanthoma tuberosum—in a healthy young man we wish to emphasize that the etiology of the various types of xanthomatosis is as yet to be determined. The knowledge of the metabolism of fats, the chemistry of cholesterol and the blood lipids with which xanthoma lesions are associated is confused and imperfect. In this report we shall attempt to discuss only briefly the various theories regarding the causes of xanthoma.

The name xanthoma was first introduced to describe a yellow fibrous or soft tumor which assumed several shapes and sizes found on the skin over various areas of the body. These tumors, which were first thought to be confined to the skin only, are now known to be present in bones, tendons and organs of the body. The orange and yellow plaques, xanthelasma, frequently noted about the eyelids, and the small pea-shaped tuberosities found on the knees and elbows are benign and more or less common. All these yellowish tubercles, papules, plaques and other shaped growths contain cholesterol and may be associated with diabetes mellitus and hypercholesterolemia.

These accumulations which we shall call in this case tubercles, may be due to many causes, such as accidents,

long continued mild trauma, inflammation, or deficiency diseases, while some are neoplastic. Not all of them are yellow, some being reddish brown, some pink and some purplish. All contain the typical foam cell, which is a special type, consisting of a large body of protoplasm with distinct borders and foamy structure. This meshy appearance is due to the removal of numerous lipid droplets in the cytoplasm, which are dissolved during the staining process. These droplets are composed largely of cholesterol and its esters.

Early observers, among them McDonagh¹ and Aschoff,² were of the opinion that xanthomatous lesions were benign neoplasms arising from the endothelial system. Rowland³ was of the opinion that all these tumors, or granulomas containing xanthoma cells, were manifestations of one disease and were due to the disturbance of lipid metabolism.

In 1929 a series of investigations was carried out by Wile, Eckstein and Curtis.⁴ They studied the lipid chemistry of the blood and the various types of xanthoma and showed definitely that they do occur in the presence of a low or normal cholesterol, as well as in the presence of a high cholesterol. Wile further pointed out that one reason for the belief that xanthoma lesions were due to a hypercholesterolemia in the past was an error in lipid chemistry. This error led to the belief that blood overloaded with fat contained a larger amount of cholesterol than it did.

This was due to the difficulty in differentiating that lipid from the other lipids of the blood. Wile and his collaborators further showed that in the absence of diabetes mellitus an increase in alimentary fat had no influence in the course of the cutaneous lesions, but an extreme reduction in the total diet brought about a remission of the nodules.

On the contrary, in the diabetic and the potential diabetic patient the cutaneous nodules disappeared when there was a fall in the value of the circulating lipids. Ingested fat did not seem to affect the involution of the lesions.

The work of Schaaf and Werner⁵ in 1930, of Bloch⁶ in 1931 and of Schaaf⁷ in 1931 has contributed much knowledge regarding the etiology of xanthoma. The observers concluded that in patients with xanthoma there exists a greater or less disturbance in the mechanism which regulated the stable emulsion of fat and lipids in the blood stream. When this balance was upset, a partial precipitation of one or more fractions occurred in order that the balance might be reestablished, the precipitated portions thus set free were stored in the tissue spaces. This regulating mechanism could not be discovered, but these investigators suggested that it might be located in the liver. It should be observed here that in the most severe liver diseases with jaundice there is very seldom found any xanthomatous diseases or lesions.

These observers made another important observation—that, in the study of patients with xanthomatous lesions, blood cholesterol or blood fat determinations alone were of no value. Fractional analyses of the various lipid constituents must be made both in fasting subjects and after the introduction of an excess load of fat and cholesterol by the test meal.

Schaaf and Werner further concluded that it seemed plausible that with a disturbance in the lipid fractions

Fig 1—Xanthoma tuberosum of the elbows and forearms. Note flat scaly lesion.

a very slight instability might exist, which might be intensified by trauma, or alteration in the tissues, thereby completing the disintegration of the emulsion and allowing fats, cholesterol and phosphatides to deposit in the skin.

Melicow,⁸ in a review of the subject of the various types of xanthoma, proposed the name xanthic lesions to cover all these different groups. This classification is very comprehensive and will be of great value for further detailed study. He mentions the generalized forms and identifies those clinical forms which come under the general head of constitutional types: (1) Niemann-Pick's disease, (2) Gaucher's disease, (3) Hand-Schüller-Christian's disease, (4) possibly, Tay-Sachs amaurotic family idiocy. These are grave constitutional disturbances, though rare in occurrence. The theory is suggested that xanthic granuloma diabeticorum, xanthic granuloma palpebrarum and multiple xanthic dermatosis might be similar constitutional disturbances, though milder in degree. This observer also mentions the hereditary tendencies, obesity and liver disease as being frequently associated with the xanthomatoses.

As various types of xanthomatous lesions are reported from time to time, the pathology becomes wider and wider in scope, apparently showing a close relationship between a simple skin disease which is harmless and a fatal constitutional disease. As an example of this, one finds within the same group Gaucher's splenomegaly and the simple yellow papule seen about the eyelids, xanthelasma.

REPORT OF CASE

History—W L, a man, aged 27, Italian, a chef examined at the Roosevelt Hospital in January 1936, had been admitted to the dermatologic clinic one month previously for examination because of the yellowish nodules on the skin of buttocks, elbows and knees. These nodules first began to appear about one and one half years previously. They were first noted about six months after he began work as a tile setter, appearing first on

the elbows and knees, where pressure was the greatest during his occupation, and later on the buttocks. When they were first noted they were pea sized and not painful to the touch, but as time passed they grew larger and caused so much discomfort, especially about the knees, that he changed his work to that of a cook. He had continued this occupation for the past year and a half. Since this change the skin lesions had not grown larger or increased in number, in fact some of the smaller ones had disappeared spontaneously and on their sites brownish pigmented spots persisted.

Physical Examination—The patient was exceptionally well developed and obese, the height was 68½ inches (174 cm) and the weight 197 pounds (90 Kg). He had gained about 40 pounds (18 Kg) in the past eighteen months. There was no history of diabetes mellitus in the family or of similar skin lesions. His only subjective complaints were that he could not concentrate on his work and would fall asleep very easily.

The past history was negative except for jaundice of three or four weeks' duration at the age of 10 years and quinsy sore throat two years before admission. The eyes were normal, and the ophthalmologic examination was negative for any fatty deposits. The ears were normal and the teeth in good condition. Large reddish tonsils were noted. A careful examination of the blood pressure, heart, lungs, abdomen and genito-urinary organs did not reveal any abnormalities. The extremities were normal and the neurologic examination did not reveal any abnormal manifestations.

The patient stated that when he first noted the nodules on the knees they were the size of a small pea, they gradually increased in size and number. Some of them fused to form larger ones, and some of those on the elbows fused to form flat ones. The tuberous lesions were typical of xanthoma tuberosum in color, contour and location. These nodules and papules were raised, round and shiny; some were soft and others hard. Several of those on the elbows (fig 1) were pea sized, others were 1.5 cm in diameter, yellowish, and somewhat scaly and hard. These were not painful on pressure but as they grew they fused and flattened. The lesions on the buttocks were more numerous than elsewhere, of a yellowish hue, and raised and varied in size from very small peas to 1 cm in diameter.

The lesions on the knees (fig 2) were most striking in appearance, especially the right knee (fig 3). The smallest pea-sized ones were yellow. Other larger ones were pink and

Fig 2—Xanthoma tuberosum of the knees.

a deeper yellow, while some of the largest ones were bluish and others purplish. The smaller ones were soft and depressible, but the larger ones were harder and fixed. Their sizes varied from 0.5 cm in diameter for the discrete ones to 1.5 cm for the largest ones, which had been formed by fusion and were somewhat flat. All were glistening in appearance. They were not painful to the touch, but the patient stated that when he knelt for any length of time these areas became red and caused discomfort. Three brownish areas are noted in the illustrations, which are the sites of those which have disappeared. At no other part of the body could any similar lesions be found. There are no evidences about the eyes, mucous membranes or tendon sheaths.

Roentgenograms of the skull, lungs and heart revealed nothing of interest, and the changes were within normal limits.

Laboratory Examination—A complete blood count and urinary examination revealed normal conditions. The blood chemistry showed blood cholesterol 170 mg and urea nitrogen 137 mg per hundred cubic centimeters. The blood sugar after ten hours' fasting was 105 mg. The blood Wassermann and Kahn reactions were negative. A dextrose tolerance test was performed with the results as follows: fasting 0.099 mg, after the first hour 0.218 mg, after the second hour 0.164 mg, after the third hour 0.078 mg per hundred cubic centimeters of blood. A second blood cholesterol was found to be 0.199 mg per hundred cubic centimeters of blood. The basal metabolic rate was found to be minus 10. The urinary examinations were negative for dextrose at all times.

Pathologic Examination—A nodule was removed from the right knee for biopsy, the report of which was as follows: The epidermis was elevated and flattened in one zone and the rete pegs were much shortened. In the corium of the adjacent region there were prominent arterioles and capillaries, yellow

Fig. 3—Xanthoma tuberosum of the right knee illustrating large elevated tubules.

pigment was noted in the large monocytes in such foci. The diagnosis was pericapillary histiocytosis of the xanthoma type. A second nodule was removed for further examination, the report of which was as follows: The hematoxylin and eosin stained specimen showed some fibrous tissue with foamy cells. The more definite changes were seen in the sections stained for fat. Here were numerous elongated spindle cells arranged in indefinite bundles, which crisscrossed. These cells contained red globules of a translucent nature (lipoid). The diagnosis was fibroxanthoma.

Course—The patient was placed on a diet of 100 Gm of carbohydrate, 50 Gm of protein and 50 Gm of fat for the following six weeks and he lost 10 pounds (4.5 Kg). There was no apparent change in the lesions during this time. The diet was difficult to control because the patient could not be under proper observation. On his return to the clinic six weeks later we found that he had gained the weight he had previously lost. During this time, however, three of the smaller nodules had disappeared entirely from the knees leaving brownish spots on the sites. The patient was then strongly advised to adhere to his diet and to have 10 units of insulin administered before each meal. On observation one month later, now four months after he was first examined there was no further apparent change in the appearance of the lesions.

Thus our efforts to influence the lesions in this case of xanthoma tuberosum in mild diabetes were without effect.

COMMENT

Several cases of xanthoma diabeticorum have been treated successfully with a low carbohydrate diet, insulin or both. Goldstein and Harris⁹ reported an excellent result with insulin, Templeton and Chouret¹⁰, Azer,¹¹ and Moreland and Dardinski¹² reported that a low diet caused the lesions to disappear. Diet combined with insulin was found of value by Engman and Weiss¹³. Gordon and Feldman,¹⁴ and Stetson and Diasio¹⁵ found diet only of temporary value in treating xanthoma multiplex. Ralli¹⁶ likewise reported that diet was of little value in a case of acromegaly associated with diabetes mellitus and xanthoma diabeticorum.

In studying the metabolism of fats and carbohydrates, and the chemistry of cholesterol and the blood lipids in relation to xanthomatous lesions, the impression is definitely obtained that knowledge is very imperfect. There are so many confusing theories, paradoxes and diverse manifestations that we consider it important to state briefly some of these observations found in the literature.

1 Hypercholesterolemia alone cannot account for the formation of xanthoma lesions, because about 30 per cent of the cases of xanthoma showed no increase in blood cholesterol.

2 Xanthoma has been frequently found in the absence of lipemia.

3 Lipemia is of frequent occurrence in tuberculosis, nephrosis and infectious diseases such as scarlet fever, typhoid and pneumonia, yet xanthoma is a rare occurrence in these diseases.

4 Xanthoma lesions do occur associated with diabetes mellitus and the prediabetic state, but they are so rare that only a few hundred cases have been reported while the number of diabetic patients run into the thousands.

5 If xanthomatous lesions are associated largely with an increased blood cholesterol, as was formerly thought, why are they so infrequently found in liver disease, in which the blood lipids are as a rule markedly increased? Wile remarked long ago that xanthomatosis was almost never encountered with jaundice.

6 Cholesterol is widely distributed and present in all types of food that are eaten daily, but it does not seem to be associated with any specific skin lesion.

7 Jadassohn, in discussing Wile's⁴ paper, reported a case of xanthoma in which the blood lipids were high but he was unable to produce new lesions by traumatizing the skin. Wile⁴ in a further discussion of Jadassohn's remarks mentioned a case in which the lesions of xanthoma had developed from such a trauma as a mosquito bite.

8 The observations of Wile and Duemling,¹⁷ Wein grow¹⁸ and Lane and Goodman¹⁹ all emphasize and

illustrate the hereditary character of xanthoma. The latter's cases illustrate the importance of trauma in producing xanthoma.⁹ Higman, in discussing the paper of Michael and Nicholas, referred to the work of Lebedev published twenty years before on experimental xanthoma. This had been produced in rabbits after they had been fed lipoids on the site where setons had been placed.¹⁰ The upset balance theory of Schaaf and Werner⁶ and Bloch⁶ seems to be accepted by many observers.

Michael,²⁰ in discussing his paper, did not think that this theory of the imbalance of lipid constituents was altogether so simple. These observers found a case of this imbalance in nephrosis and one in acute yellow atrophy of the liver, in neither instance was there any evidence of xanthoma deposits.

We have presented the conflicting opinions and observations found in the study of this case of xanthoma tuberosum and mild diabetes mellitus with the hope that more extensive investigation of the entire subject of metabolism of fats and carbohydrates, in their relation to dermatology, will be carried on.

CONCLUSIONS

We have made three observations in reporting this case of xanthoma tuberosum in a young man which may throw some light on the etiology of this uncommon skin lesion.

1 The patient was quite obese and had consumed large quantities of fat in his diet for many years, eating as much as a pint of gravy a day for the past several years.

2 His occupation as a tile setter for a period of over two years may have traumatized the elbows and knees. The nodules did not appear until after he began this type of work, and they increased in size and number during that time only.

3 The case might be classed by some clinicians as prediabetic or latent diabetic. The blood sugar readings were 0.218 mg at the end of the first hour and 0.164 mg at the end of the second hour. The urine did not show the presence of dextrose at any time.

In reporting this case of xanthoma tuberosum, possibly in a patient with mild diabetes who has been subjected to chronic traumatism, the question arises with what are we dealing? Are we dealing with a simple disease of the skin due to some unknown metabolic disturbance, or is this a mild form of some grave constitutional disease?

The Change in Surgery—An entire change in the character of operative workmanship largely explains the transformation in the surgery of the past decade or two. The accurate and detailed methods in the use of which Kocher and Halsted were for so long the notable examples have spread into all clinics—at least into those clinics where you or I would wish to entrust ourselves for an operation. Observers no longer expect to be thrilled in an operating room, the spectacular public performances of the past, no longer condoned, are replaced by the quiet rather tedious procedures which few, beyond the operator, his assistants and the immediate bystanders can profitably see. The patient on the table like the passenger in a car, runs greater risks if he have a loquacious driver or one who takes close corners exceeds the speed limit, or rides to applause—Cushing, Harvey, Consecration, Medici and Other Papers Boston, Little, Brown & Co., 1928.

THE EFFECT OF FLIGHT ON THE MIDDLE EAR

HARRY G. ARMSTRONG, M.D.
Captain Medical Corps United States Army

AND
J. W. HEIM, Ph.D.
DAYTON, OHIO

Those familiar with aviation medicine are well aware that airplane pilots suffer more frequently from disturbances of the middle ear than from all other occupational diseases combined.¹

The phenomenal growth of commercial air transport, which carried approximately one million passengers in 1936, makes this problem of interest and importance to the general medical profession, for airplane passengers are exposed to the same influences as the pilots during flight and in most instances are much more adversely affected.

ANATOMY AND PHYSIOLOGY

Since the deleterious effects of flight on the middle ear depend entirely on the peculiar structure and functioning of the eustachian tube, a brief anatomic, normal physiologic and special physiologic review of the latter structure will be presented.

Anatomy—The eustachian tube is a slitlike, potential tube extending from the middle ear to the nasopharynx. It is formed of bone, cartilage and fibrous tissue.

The bony portion begins at the upper part of the anterior wall of the tympanic cavity and, gradually narrowing, passes downward, forward and medially for about 12 mm, ending at the angle of the junction of the squamous and petrous portions of the temporal bone.

The cartilaginous portion of the tube extends from the bony portion to the nasopharynx. This section is about 24 mm in length and is formed of a triangular plate of elastic fibrocartilage with its apex attached to the bony portion and its base placed directly under the mucous membrane of the nasopharynx, where it forms a prominence, the torus tubarius. The upper edge of the cartilage is bent laterally and takes the form of a hook on cross-section, open below and laterally. These walls of the canal are completed by fibrous tissue.

The lumen of the eustachian tube is narrowest at the junction of the bony and cartilaginous portions, the isthmus, and expanding rapidly in both directions reaches its largest diameter at the pharyngeal orifice. At rest, the lumen of the cartilaginous portion of the tube is a vertical slit with its walls opposed.

The mucous membrane of the eustachian tube is a direct extension of that of the nasopharynx and continues backward to line the middle ear completely. The mucous membrane of the bony portion of the tube is thin, but in the cartilaginous portion it is thick and very vascular, contains numerous mucous glands and is composed of ciliated columnar cells. Near the mouth of the eustachian tube is a variable amount of adenoid tissue known as Gerlach's or tubal tonsil. The pharyngeal ostium of the eustachian tube is located high up on the lateral wall of the nasopharynx. This opening is triangular, bounded behind by the torus tubarius and in front by the nasal cavity.

The muscles that are attached to the eustachian tube and their actions are as follows

1 *Levator veli palatini* Origin inferior aspect of the pyramidis ossis temporalis and from the lateral end of the medial lamina of the eustachian tube Insertion downward, medially and forward parallel to the inferior margin of the medial lamina of the eustachian tube, uniting in the soft palate with the corresponding muscle of the opposite side Action elevates the soft palate, narrows the eustachian ostium and dilates the isthmus

2 *Tensor veli palatini* Origin scaphoid fossa of the sphenoid bone, lateral and membranous lamina of the eustachian tube and angular spine of the sphenoid bone Insertion the fibers run downward and forward around the sulcus of the pterygoid hamulus and radiating medially into the soft palate it attaches to the hard palate and to the corresponding muscle of the opposite side Action tenses the soft palate and opens the eustachian tube

3 *Salpingopharyngeus* Origin inferior part of the ostium of the eustachian tube Insertion blends with the posterior fasciculus of the pharyngopalatinus muscle Action raises the upper and lateral parts of the pharynx opens the ostium of the eustachian tube

Fig 1—Gross anatomy of the eustachian tube showing (A) longitudinal section (B) cross section near the eustachian ostium and (C) the ostium of the eustachian tube in its relation to the surrounding structures

The gross anatomic features of the eustachian tube are shown in figure 1

Normal Physiology—The eustachian tube drains the middle ear and ventilates it. The motion of the cilia and the flutter-valve like action of the tube favors the motion of material from the ear to the nasopharynx and opposes motion in the opposite direction. The tube, while normally closed, is opened by contraction of its dilator muscles and at such times any air pressure differential existing between the middle ear and the atmosphere is equalized. This contraction may occur during swallowing, yawning and other similar physiologic acts.

Special Physiology—Aircraft flights involve changes in altitude and this in turn involves changes in atmospheric pressure, the relationship between the two being as shown in figure 2. It is to be noted that with ascent, equal changes of pressure involve increasing intervals of altitude. The rates and degrees of atmospheric pressure changes during flight depend on the rates and degrees of ascent or descent, and these factors become important when it is remembered that the ear is an air-filled closed cavity with pressure equalization possible only when the eustachian tube is opened.

Since the physiology of the eustachian tube under marked variations of atmospheric pressure had never been previously reported, we carried out laboratory investigations of this problem on five healthy men covering pressure variation rates of from 54 to 27 mm of mercury per minute (200 to 1,000 feet per minute) through pressure ranges of from 760 to 141 mm of mercury (0 to 40,000 feet altitude).

The results of this study were briefly as follows. Beginning at sea level pressure and decreasing the pressure at a constant rate, a pressure change of from 3 to 5 mm of mercury (110 to 180 feet altitude) was required before any effect was perceptible in consciousness. At this point there appeared a slight sensation of fulness in the middle ears and examination showed the tympanic membranes to be slightly bulged. This bulging and the sensation of fulness increased with the decreasing of pressure until at 15 mm of mercury (500 feet altitude) differential there was a sudden annoying "click" heard and felt in the middle ear, the drum snapped back to or almost to, normal position and the sensation of fulness disappeared. The eustachian tube had been forced open by the excess pressure in the tympanic cavity and the ear pressure relieved by a sudden rush of air from the ear to the nasopharynx.

During the remainder of the pressure decrease this cycle was repeated except that all succeeding "clicks" occurred at intervals of only 114 mm of mercury (435 feet altitude) pressure change. This indicated that it requires 15 mm of mercury excess pressure in the middle ear at sea level conditions to force the eustachian tube open and that it remains open until the pressure is reduced to about 36 mm of mercury, when it again closes, leaving 36 mm of mercury (130 feet altitude) excess pressure in the ear. It had been assumed that, since the pressure altitude curve is not a straight line (fig 2), the eustachian tube would open at equal intervals of pressure but at increasing

intervals of altitude during ascent. Actually the reverse was found to be true, the tubes opening at 425 feet intervals (except the first), which amounts to 114 mm of mercury pressure at sea level but only 35 mm at 40,000 feet. The explanation of this phenomenon is probably based on the fact that air of the higher altitudes, being less dense, passes more readily through the eustachian tubes. These figures are averages based on repeated tests. Actually there was considerable variation between individuals and in the same individual. These variations ranged from 5 to 30 mm at sea level conditions, but the averages for individuals were remarkably constant.

When the atmospheric pressure was increased instead of decreased, a totally different effect was obtained. Here the eustachian tube, acting like a flutter valve remained closed under all degrees of pressure (one subject tested to —470 mm of mercury pressure) and the tympanic membrane finally ruptured.

In the course of these studies, swallowing and other voluntary efforts to open the eustachian tubes were suppressed. However, in a subsequent series of tests it was found that opening the eustachian tubes by voluntary effort immediately equalized the ear pressure completely except that, after a negative pressure of from

80 to 90 mm of mercury or more had developed in the tympanic cavity, it was then impossible for the eustachian muscles to overcome the negative pressure which held the fibrocartilaginous portion of the eustachian tube tightly collapsed, and it was then necessary to decrease the atmospheric pressure below that point before the eustachian tubes could again be voluntarily opened

TERMINOLOGY

Since the condition being discussed is already a recognized occupational disease and seems destined to become of general professional concern, it seems logical to suggest a proper terminology

In the United States the term "aviator's or aviation ear" has begun to appear in the literature, while in Germany the terms "barotrauma" and "tonetrauma" have been suggested. The former are obviously unsuitable and the latter may be criticized as not being descriptive of the disease. We therefore suggest "aero-otitis media" (aero, combining form from the Greek *αἴρ*, *aḗros*, air, + *otic*, Greek *ωτικός*, pertaining to the ear, + *itis*, Greek *ιτις*, inflammation of) as a suitable descriptive term for the new clinical entity about to be described, and that term will be used throughout the remainder of this paper

DEFINITION

Aero-otitis media is an acute or chronic, traumatic inflammation of the middle ear caused by a pressure difference between the air in the tympanic cavity and that of the surrounding atmosphere, commonly occurring during changes of altitude in airplane flights and characterized by inflammation, discomfort, pain, tinnitus and deafness

ETIOLOGY

Aero-otitis media is due to the lack of ventilation of the middle ear during changes of atmospheric pressure to the extent that the tympanic cavity is traumatized. There are two principal causes of improper middle ear ventilation: one a failure to open the eustachian tube voluntarily when necessary, the other the inability to open it.

Failure to open the eustachian tubes during changes in altitude in aircraft flights is most often due to ignorance of the necessity to do so but may be due to carelessness or to being asleep or may arise from the influence of analgesics or anesthetics or from coma. The first two of these instances usually occur among inexperienced pilots and passengers, the third in sleeper airplanes, and the last group on ambulance planes.

Inability to ventilate the middle ear voluntarily is much more prevalent than is generally recognized. Some of the most frequent causes of eustachian stenosis are acute and chronic infections of the upper respiratory tract, nasal obstructions, sinusitis, tonsillitis, tumors and growths of the nose and nasopharynx, paralysis of the soft palate or superior pharyngeal muscles, enlargement of the pharyngeal or tubal tonsil, inflammatory conditions of the eustachian tube or middle ear, scar tissue about the ostium of the eustachian tube following adenectomy, and malposition of the jaws.

The latter two conditions have but recently been recognized. Simpson² states that he has frequently seen considerable scar tissue about the pharyngeal ostium of the eustachian tube as the result of adenectomy when the adenotome had been allowed to pass too far laterally, causing trauma or laceration to the torus tubarius.

The effect of malposition of the mandible in relation to stenosis of the eustachian tube was first reported by Costen³ and later applied to aviation by Willhelmy. They showed that in individuals with endentulous mouths, ill fitting dental plates, marked overbite malocclusion, worn or lack of molar teeth either unilateral or bilateral or with any other condition in which there was a shortening of the vertical position of the lower jaw a compression-stenosis of the eustachian tube was likely to occur from a relaxation of the surrounding soft tissues.

SYMPTOMATOLOGY

The symptoms of aero-otitis media depend on the duration, frequency and severity of the trauma sustained.

Aero-Otitis Media, Acute—Subjective Symptoms. Positive pressure of from 3 to 5 mm of mercury in the middle ear are perceptible in consciousness to most individuals as a feeling of fullness in the middle ear. At about 10 to 15 mm of mercury pressure the feeling of fullness is distinct and somewhat annoying and affects

Fig 2—Altitude pressure curve

the hearing by imparting a distant sound and a lessened intensity. Pressures between 15 and 30 mm of mercury usually increase the discomfort and may be accompanied by tinnitus. The latter is of a steady hissing or roaring character or crackling and snapping. In some individuals there may be actual pain and vertigo of a mild nature. Above 30 mm of mercury pressure in the middle ear there is increasing pain, tinnitus and vertigo, which finally becomes unbearable.

In normal cases about 15 mm of pressure is sufficient to force air out through the eustachian tube, which relieves the pressure in the tympanic cavity and consequently the accompanying symptoms. However, this relief is initiated by an annoying "click," which is both felt and heard as the drum snaps back to normal position. In stenosis of the tube the pressure required to force it open varies with the degree of stenosis. In these cases the pressure may be relieved gradually over a period of time instead of instantaneously, and a greater amount of pressure remains in the middle ear after the tube has again closed.

In descent, in which the atmospheric pressure is increasing and the pressure in the ear becomes negative the symptoms are the same as already described except

3 Costen J B. A Syndrome of Ear and Sinus Symptoms Dependent upon Disturbed Function of the Temporomandibular Joint. *Ann Otol Rhin & Laryng* 43:1 (March) 1934.

4 Willhelmy G E. Ear Symptoms Incidental to Sudden Altitude Changes and the Factor of Overclosure of the Mandible. Preliminary Report U S Naval M Bull 34 533 541 (Oct) 1936.

2 Simpson R K. Personal communication to the authors.

that the pressure is never relieved through its own force acting on the eustachian tube because of the flapper-valve like action of the latter. For this reason the greatest difficulty usually occurs during descent in aircraft, and the highest pressure differentials have been seen and studied experimentally under this condition. At about 60 mm of mercury negative pressure the pain in the ear is severe and resembles that of acute otitis media. The tinnitus is marked and there is usually vertigo with beginning nausea. At from 60 to 80 mm of mercury negative pressure the pain is very severe and radiates from the ear to the temporal region, the parotid gland and the cheek. Still higher pressures produce agonizing pain, which seems to localize not in the ear but deep in the substance of the parotid gland. Deafness is marked and vertigo and tinnitus usually increase, but the latter may disappear. At between 100 and 500 mm of mercury pressure the tympanic membrane ruptures.

This occurrence is a dramatic episode in which the patient feels "as though hit along the side of the head with a plank," a loud explosive report is felt and heard in the affected ear, there is a sharp piercing pain on the affected side, vertigo and nausea become marked and collapse or generalized shock follows. With rupture of the tympanic membrane the acute pain quickly subsides, but a dull ache persists for from twelve to forty-eight hours. Hearing is distinctly diminished and vertigo and nausea may persist for from six to twenty-four hours.

With both positive and negative pressures, voluntarily opening the eustachian tube will immediately relieve all acute symptoms, but it is to be remembered that with a negative pressure in excess of about 80 or 90 mm it becomes impossible to overcome this by muscular action, and relief is obtained only by a return to a higher altitude and a pressure difference of less than from 80 to 90 mm of mercury. In cases in which the pressure has already produced trauma, opening the eustachian tube will not relieve the symptoms of that trauma, and they persist until recovery has taken place. The symptoms following trauma to the middle ear depend on the extent and duration of the trauma. Pressures that may be only uncomfortable at first finally become painful. Moderate trauma to the ear is followed by a sense of soreness in the ears and deafness lasting from one to twelve hours. Severe trauma is followed by pain, deafness, vertigo and tinnitus for from four to forty-eight hours. The pain is similar to that of suppurative otitis media, the tinnitus usually of a hissing or roaring character, the deafness of the conduction type and qualitative as well as quantitative.

Objective Symptoms. The objective signs depend on the amount of trauma sustained. In mild cases the drum may appear normal except for a moderate degree of bulging or retraction when a small amount of pressure differential still persists. An increased pressure in the tympanic cavity is denoted by a bulging of the tympanic membrane with a decrease or loss of the light reflex.

A negative pressure in the tympanic cavity is denoted by a retraction of the tympanic membrane with a decrease in size and brilliance of the light reflex and an increased prominence of the short process of the malleus with a foreshortened and more horizontal handle.

Following more severe trauma the drum may be retracted or bulging as already described, and in addition

there is also an inflammation, which in appearance varies from a slight pink tinge to an angry red. In all cases the inflammation is most marked along the larger vessels that follow the malleus handle and around the drum periphery. When the inflammation is severe it cannot be distinguished from acute infectious otitis media and has frequently been mistaken for it.

Traumatic ruptures of the tympanic membrane are usually linear and quite extensive and may involve any portion of it. The margins of fresh ruptures are red and the whole drum is highly inflamed. There is usually a small amount of blood in the external auditory canal. If the labyrinthine wall is visible through the freshly ruptured drum membrane, it is seen to be red, congested and swollen.

Audiometer tests show a variable diminution of hearing, depending on the severity of the injury.

Aero-Otitis Media, Chronic.—**Subjective Symptoms.** In these cases there is a "full and stuffy" feeling in the ears and difficulty in "clearing" them. There is a partial loss of hearing, which is either unilateral or more pronounced on one side and in some instances may vary from day to day. Head noises may be present, but rarely vertigo or pain. The condition is worse after flights, during acute infections of the upper respiratory tract, during changes of weather and during fatigue or debilitated states.

Objective Symptoms. The ear drums are bulging or retracted, usually the latter. The drum membrane is dull, lusterless and slightly thickened and the light reflex is diminished or absent. Hearing acuity is diminished either unilaterally or bilaterally, and in the latter case there is usually a considerable difference between the two sides. This deafness is of the conduction type, the lower tones of the scale being lost first. Rinne's test is negative, Weber's test is positive and bone conduction is prolonged beyond the normal. Examination of the ostium of the eustachian tube shows the presence of a chronic inflammatory process or a mechanical obstruction.

DIAGNOSIS

The diagnosis of aero-otitis media is simple only if the history is known. The different traumatic inflammatory stages closely resemble the various stages of infectious otitis media and, as previously stated, have frequently been mistaken for it. Likewise, chronic aero-otitis media may be easily mistaken for a chronic infectious middle ear process unless a history of exposure to repeated changes of altitude is obtained.

COMPLICATIONS

While trained pilots usually try to avoid flying during periods when they have an acute infection of the upper respiratory tract, because of the discomfort and pain in the ears which almost invariably occurs, nevertheless a considerable amount of such flying has been done. It might naturally be expected in these cases that during descent the intermittent blasts of air from the pharynx to the tympanic cavity would carry with it septic material to the mechanically irritated tympanum and readily set up an acute inflammatory process. While it is possible or even probable that this septic material is carried into the tympanum we have never seen it, nor are there any reports in the literature of this having occurred.

TREATMENT

Prophylaxis.—Those who take up aviation as a profession are, and should continue to be, carefully tested for patency of the eustachian tubes. This may readily

be done by means of the Politzer bag. Those who have stenosis of the tube should be examined for chronic infection of the ear, sinuses, nose and pharynx, the mouth of the tube inspected for mechanical obstructions and the eustachian tube catheterized if necessary. When any of these conditions are found and corrected, it is likely that the tube will become normal. Persons examined during periods of an acute infection of the upper respiratory tract should be reexamined after the infection has subsided before a final decision is made.

Probably the most useful prophylactic measure in all cases is proper instruction of the individual concerned. As long as the patency of the eustachian tube is under voluntary control there is no reason why any person in command of his faculties need experience difficulty at any rate of ascent or descent possible in present commercial aircraft. A simple explanation of the functioning of the eustachian tube followed by instructions as to how to ventilate the tympanum, when to ventilate it and how frequently this as necessary should suffice. Probably the simplest maneuver to actuate the normal eustachian tube is to swallow. It may also be accomplished by yawning, by singing, by shouting, by autoinflation and by contracting the salpingopharyngeal muscles. The last named defies description and can be learned only by practicing the suppression of a simulated yawn, at which time a roaring in the ears will indicate when the effort is successful.

Since the average person swallows involuntarily about every sixty to seventy-five seconds, it can be seen that a rate of climb or descent of 200 feet per minute will usually cause no discomfort, 500 feet per minute slight discomfort and 1,000 feet per minute moderate discomfort even though no effort is made to ventilate the tympanum artificially. Descents above 4,000 feet per minute may catch an individual unaware and create a tympanic vacuum which it is impossible to relieve by any method except a return to higher altitudes.

Chewing gum, eating, drinking or inhaling oxygen reduces swallowing to intervals of from one to thirty seconds. Sleeping and comatose individuals swallow at increased intervals and present a serious problem.

The allowable rate of ascent and descent of commercial airlines is set by the department of commerce at 300 feet per minute, and some such companies limit themselves to 200 feet per minute, although unusual conditions such as weather may require that both of these rates be exceeded to insure the safety of the flight. Those who are suffering from either temporary or permanent stenosis of the eustachian tube should be enjoined from flying except under controlled conditions of gradual changes of altitude through a maximum range not to exceed 2,000 feet. Those with an acute infection of the upper respiratory tract who insist on aerial flights should be prepared by gargling hot physiologic solution of sodium chloride or by having a detergent spray directed well back into the nasopharynx followed by the instillation or inhalation of atropine, ephedrine or benzedrine compounds.

Active Treatment—Relief of pain is the first consideration in acute cases. The tympanum should be gently inflated by Politzer's method if the drum indicates the existence of either positive or negative pressure. Heat, dry or wet, is very effective. The instillation of copious quantities of water into the external auditory canal at from 110 to 115 F followed by dry heat is the method of choice. Inflammation of the ostium of the eustachian tube requires treatment, and hot saline gargles followed

by the instilling or mopping of astringents over that area will shorten the period of discomfort. In severe cases analgesics and even the injection of morphine, from one-eighth to one-fourth grain (0.008 to 0.016 Gm), may be necessary for the first twenty-four hours.

The after-treatment consists of the application of dry heat to the ear and the inhalation or instillation of astringents into the nasopharynx every four hours. A plug of cotton in the external canal seems to add to the comfort, especially during cold weather.

If the condition does not subside materially in twenty-four hours, acute infectious disease of the middle ear should be suspected or a stenosis of the eustachian tube looked for and corrected.

Ruptures of the tympanic membrane should be left alone and treated expectantly.

In chronic aero-otitis media, stenosis of the eustachian tube should be looked for and treatment directed to its relief. Chronic infections of the ear, tonsils, sinuses, nose and pharynx should be considered as possible causative factors and corrected. Mechanical obstruction of the eustachian ostium or tube should be removed. If there is no apparent infection and no obvious obstruction of the tube, a malposition of the lower jaw with compression of the tube may be assumed and the jaw temporarily repositioned by the technic of Willhelmy⁴ for clinical test and, if successful, permanent measures applied.

The eustachian stenosis having been relieved, the chronic inflammatory process in the tube and middle ear usually subsides spontaneously, but this may be hastened by gentle inflation of the ear or if the congestion is marked, by the application of heat to the external ear and nasopharynx. Until the condition is entirely relieved, flying should be avoided as a potential source of irritation.

PATHOLOGY

In acute cases the first change is a passive hyperemia of the mucous membrane of the middle ear and eustachian tube from negative pressures or an ischemia from positive pressures. On relief of the pressure in either case there follows a period of active hyperemia, the degree and duration depending on the severity and duration of the trauma. With high pressures actual traumatic inflammation takes place accompanied by a serous exudate. The mucous membrane becomes congested and swollen, the eustachian tube blocked and the tympanic cavity a closed cavity. The epidermal layer of the tympanic membrane takes part in the reaction and becomes inflamed and may rupture.

Chronic aero-otitis media depends on frequently repeated insults to the tympanic cavity in which the tympanic membrane and the mucous membrane of the middle ear and of the eustachian tube become chronically congested and thickened.

The pain in aero-otitis media is not only local in origin but in severe cases may reflexly or directly affect the facial nerve and its branches and thus produce a neuralgic-like pain which radiates over the distribution of that nerve.

SUMMARY

A new clinical entity is presented which consists of a traumatic inflammation of the middle ear caused by a pressure difference between the air in the tympanic cavity and that of the surrounding atmosphere, commonly occurring during changes of altitude in airplane flights and characterized by inflammation, discomfort, pain, tinnitus and deafness.

A CLINICAL INVESTIGATION OF HISTIDINE THERAPY IN CASES OF PEPTIC ULCER

ROY UPHAM, M.D.
AND
HARRY BAROWSKY, M.D.
NEW YORK

The efficacy of histidine hydrochloride as a therapeutic agent in the treatment of peptic ulcer should be given careful consideration because, despite the existing uncertainty concerning its therapeutic value, there is still a tendency among some physicians to use this remedy. The interest in its therapeutic value is largely the result of the great number of encouraging reports which have appeared in medical literature, although more recent studies have not been so favorable.

To appreciate fully the status of histidine hydrochloride, a knowledge of the literature on the subject is essential. However, because this is voluminous, only the more important contributions will be discussed.

Mann and Williamson¹ have for a number of years carried on experiments, on the intestinal tract of dogs, in transplanting the duodenal secretions to the terminal end of the ileum. As a result of such an operation, "post-pyloric ulcers of the subacute or chronic type similar pathologically to those found in man, were noted, usually in two to four weeks," and the animals also showed other serious effects, such as loss of weight, diarrhea and melena. These authors expressed the opinion that the "diversion of the secretions which neutralize the gastric juice as it leaves the stomach to another portion of the gastrointestinal tract was the cause of the peptic ulcer formation."

In 1933 Weiss and Aron,² using the same technic, reasoned that such an operation prevents further enzyme action, especially proteolytic on the food coming from the stomach, and thus produces an amino acid deficiency which is responsible for the formation of ulcer. Using dogs as controls, they tried the amino acids not synthesized by the body (lysine, tryptophan, histidine and cystine) and discovered that the animals that were given parenterally histidine and tryptophan or histidine alone did not acquire ulcers, although they did have severe constitutional symptoms, such as anemia, loss of weight and diarrhea. Autopsies were performed at the end of three and six weeks on the control dogs that were not treated, and peptic ulcers were observed in both.

The same investigators³ then applied this treatment clinically to a number of patients and reported excellent results. The favorable reports of Weiss and Aron stimulated a number of other investigators to apply histidine therapy clinically. Most of the European clinicians, although each of them had only a small series

of cases, were highly enthusiastic about this form of treatment. Among those reporting excellent results were Blum,⁴ Lenormand,⁵ Hessel,⁶ Bogendorfer,⁷ Spencker⁸ and Smith⁹.

A number of investigators who studied larger series of cases were not as enthusiastic about their results as this group. However, the results that they obtained seemed to favor the use of the product. The first large series—fifty-two cases—was reported by Bulmer¹⁰ of England. In thirty-five cases the ulcers were gastric and in seventeen duodenal. Bulmer obtained 58 per cent of symptomatic and x-ray cures and 19 per cent of clinical improvement with no definite x-ray improvement, and had 23 per cent of failures. He concluded that his patients with gastric ulcer responded more readily than those with duodenal ulcer.

Among the first observers in this country to use histidine were Volini and McLaughlin,¹¹ who, in their initial report, on twenty-one cases, indicated a very favorable response in all the patients treated by this form of therapy. They noted a decrease of gastric acidity in most of them. In a later report,¹² on seventy-three cases, the results described were also favorable. A six months check-up revealed that 79 per cent of the patients were clinically improved and that the treatment of 21 per cent was regarded as a failure, but the results of x-ray examination in only twenty-seven cases became negative for ulcer. Eads,¹³ describing a series of thirty-five cases—thirty of duodenal and five of gastric ulcer—reported six cases in which there was clinical and x-ray evidence of immediate healing, eight in which there was clinical but not x-ray evidence of improvement and twelve in which the use of histidine was a failure. Rafsky¹⁴ and others have also reported favorable results with the use of histidine hydrochloride.

However, more recent studies do not substantiate the favorable results obtained by the early investigators. Sandweiss,¹⁵ for example, treated sixty-seven patients suffering from peptic ulcer, fifty-three of them with a modified Sippy regimen and forty with histidine. Histidine produced remission of symptoms in 50 per cent and the modified Sippy treatment in 51 per cent. However, in a six months follow-up study, 85 per cent of the histidine-treated patients had recurrences, as compared to only 31 per cent of the patients treated with diet and alkalis. As controls, he treated twenty patients by daily injections of 5 cc of distilled water, and 60 per cent became symptom free. In conclusion he stated that the routine use of histidine in the treatment of peptic ulcer is not advisable. However, it may

be used for patients who do not respond to a regimen involving diet, alkalis and antispasmodics because about 50 per cent of such patients became symptom free and an additional 20 per cent were moderately improved. In a later study, Sandweiss¹⁶ concluded that histidine and other forms of injections may produce remissions, but he expressed the opinion that such remissions are due either to "psychic effects" or to "the intermittent nature of the disease." He admitted, however, that most of the patients treated with parenteral injections were on a diet similar to diet 3 (a modified Sippy diet) at the time that treatment was begun and that the administration of alkalis was continued if it had been begun before the injection treatment was instituted.

At the request of the Council on Pharmacy and Chemistry of the American Medical Association, Martin¹⁷ treated forty-one patients with histidine and forty control patients with a modified Sippy regimen. Of the former, twenty-eight were treated with "Larostidin" (Hoffmann-LaRoche) and thirteen with a 4 per cent aqueous isotonic solution of histidine hydrochloride. The results in the two series were similar, 73.2 per cent of the patients treated with histidine and 78.4 per cent of the control patients obtained symptomatic relief. The frequency of relapses in both series was also similar. For example, in a period of observation of from six months to one year, relapses occurred in twenty-six of the histidine-treated patients and in twenty-four of the control group.

"As a result of its consideration of the paper of Martin and others," the Council concluded that, "although there is at present insufficient clinical evidence for its evaluation, histidine hydrochloride shows promise of possible usefulness in the treatment of gastric and duodenal ulcer." However, the Council declared that "Larostidin" (Hoffmann-La Roche, Inc.) was not acceptable for New and Nonofficial Remedies because of the fact that it was marketed with unwarranted therapeutic claims, and it was voted to postpone further consideration of histidine monohydrochloride until adequate clinical evidence of its therapeutic usefulness was available.

Furthermore, not only clinical but experimental evidence as well fails to support the claims made for histidine therapy in cases of peptic ulcer. This was conclusively pointed out by Fontes and Bauer,¹⁸ in experiments which they carried out on dogs, and by Barry and Florey,¹⁹ using the operation of Meckel's diverticulum. The work of Flood and Mullins²⁰ and the experimental researches of Sandweiss, Saltzstein and Glazer²¹ also failed to corroborate the results obtained by Weiss and Aron.

A survey of the literature on the subject reveals the interesting fact that recent investigators do not agree with the highly enthusiastic reports of a large number of early research workers. In fact, they point out that histidine therapy is even less beneficial than the accepted diet-alkali regimen.

Because a careful study of the cases reported shows that the majority of patients who were treated with histidine were at the same time on some form of a modified Sippy treatment, either at the beginning or throughout the course of their treatment, a more exact study seemed imperative. In a clinical study it is extremely difficult to gauge accurately the beneficial effect that the patient receives from this type of therapy because a number of factors are involved which are difficult of control. Therefore, the authors felt that to determine the therapeutic value of this remedy it was essential to rule out as many as possible of the factors that would influence the healing of the ulcer. To accomplish this, a graduated form of therapy was instituted, and to substantiate the study further, a control series of experiments was performed on a similar group of patients.

CLINICAL MATERIAL

Uniformity of clinical material was sought. Practically all the patients presented a similar social background, the majority of them being of foreign extraction, having language difficulty and being subsidized by the Home Relief Bureau. They were all men and ranged from 22 to 52 years of age. Only patients with duodenal ulcer were selected. All were ambulatory. The majority presented the typical duodenal ulcer syndrome, and all had definite hyperacidity. On x-ray examination, all showed the characteristic "duodenal cap deformity." A large percentage of the patients had ulcers of the chronic recurrent variety and had had some other type of therapy previously.

GRADUATED METHOD OF STUDY

The method employed consisted of the daily intramuscular injection of 5 cc of the solution, one group receiving histidine and the control series receiving sterile water. The hypodermic injections were administered by the clinic nurse, and a series of twenty-four injections was given daily.

Fifty patients were treated by this method, twenty-five receiving histidine solution ("Larostidin") and twenty-five receiving sterile water. At the beginning of the treatment all other therapeutic factors, such as diet and the administration of alkalis and antispasmodics, were eliminated. The patients were instructed to remain on a liberal diet. However, if at the end of the first week marked relief was not obtained, they were advised to stay on a modified Sippy diet. At the end of the second week, if they still complained of symptoms, antacids and antispasmodics were added. The majority of the patients welcomed this form of therapy and cooperated to a greater degree than when they received the classic diet-alkali treatment.

RESULTS

In the histidine series, only one of the twenty-five patients studied was completely relieved by the injection treatment. This patient remained on a nonrestricted diet throughout his course of therapy. Twenty-four patients still had definite symptoms at the end of the first week, and these were put on a modified Sippy diet. In this group of twenty-four, thirteen obtained from marked to complete relief within twenty-four to forty-eight hours. At the end of the second week the administration of antispasmodics and antacids to the remaining eleven was begun, but only three obtained definite relief. No relief was obtained by the remaining eight throughout the course of treatment.

21 Sandweiss D J Saltzstein H C and Glazer W S The Value of Histidine in the Prevention of Experimental Ulcer in Dogs Am J Digest Dis & Nutrition to be published

The same procedure was followed with the control series. In a group of twenty-five patients treated with sterile water, three obtained complete relief of symptoms despite the fact that they were on a liberal diet throughout the course of treatment. These patients received no other type of therapy. At the end of the first week, the remaining twenty-two were put on a modified Sippy diet because they still had symptoms. Fourteen obtained from marked to complete relief in from twenty-four to forty-eight hours, and two others were definitely relieved on the addition of antacid and antispasmodics, at the end of the second week. Six patients failed to respond to any form of therapy.

In a follow-up study varying from six months to one year, it was noted that ten of the histidine-treated patients had relapses and that eleven of the control series had remissions.

A comparative study of the gastric chemistry was made at the beginning and at the termination of the course of injections but failed to demonstrate any appreciable uniform improvement. Although in some

Response to Graduated Form of Therapy

	Histidine	Sterile Water	Combined
Total cases treated	25	25	50
Marked relief obtained solely from injections	1	3	4
Marked relief obtained only when a modified Sippy diet was added to the treatment at end of first week	13	14	27
Definite relief obtained only when antispasmodics and antacids were added to the treatment by injection and diet at end of second week	3	2	5
Total number responding to treatment	17	19	36
Failures	8	6	14
Follow up, from six months to one year, number of recurrences	10	11	21

cases there was a decrease in free hydrochloric acid at the termination of treatment, in a corresponding number there was an increase. One may expect to find such variations in the chemistry of the stomach of the same person on different occasions. This was convincingly pointed out by Alvarez, Van Zant and Osterberg.²²

X-ray study is of great diagnostic value in cases of duodenal ulcer but proved of little importance in evaluating the healing of the ulcer in our cases. It was repeatedly demonstrated that despite the fact that the patient was symptom free for as long as three months, "duodenal cap deformity" tended to persist in most of the cases.

COMMENT

The graduated form of study, substantiated by a control series, eliminates to a great extent the accepted therapeutic aid which diet, antispasmodics, alkalis and rest give to the patient suffering from peptic ulcer and places histidine therapy to a marked degree on its own merit. Previous investigators did not completely eliminate these therapeutic factors.

However, before giving credit to any form of therapy for the results obtained in any case of peptic ulcer, one must take into consideration several important facts which influence the prognosis. Periodicity of the attacks is characteristic of the disease, and the response to therapy depends therefore in great measure on the duration of the attacks. One may assume that

a goodly percentage of the patients who do not improve after a month's treatment will become symptom free if another form of therapy is instituted. Patients with shorter histories tend to react more quickly and more favorably than those with longer histories. The same holds true for the age of the patients, the younger the patient, the better the response to therapy. It has also been observed that gastric ulcers have a tendency to heal more rapidly than duodenal ulcers. Pathologic factors, such as the degree of scarring, periduodenal adhesions and possible associated duodenitis have an important role. The etiologic factors must also be accorded due consideration. In evaluating the results of the therapy of peptic ulcer, it is extremely important to realize that these factors have a direct influence on the prognosis in a given case and that the therapeutic agent employed is of only secondary importance.

A number of investigators have offered several plausible theories for the good results obtained with histidine therapy. However, in evaluating the results of our studies, we prefer to favor the explanation that the beneficial effects obtained with histidine were merely the response to a form of psychotherapy. This assumption is well borne out when it is considered that four of our patients, three of whom received injections of sterile water, responded very rapidly—within twenty-four to forty-eight hours—to the parenteral therapy alone. This theory was frequently demonstrated to our satisfaction, especially in the group that received sterile water. As soon as the injections were stopped a certain number of the patients had a recurrence of symptoms, and as soon as parenteral therapy was resumed their pain disappeared. It is justifiable to conclude from the results of this study that a certain proportion of patients who have no complicating pathologic conditions will be amenable to some form of psychotherapy. Consequently, credence must be given to the increasingly popular conception that peptic ulcers frequently are merely local manifestations of a generalized psychogenic disease.

SUMMARY

A brief survey of the literature on the use of histidine in the treatment of peptic ulcer revealed the interesting fact that the extremely favorable results reported by early investigators have not been borne out by more recent experimental and clinical research.

With the use of a graduated form of therapy, it was found that the majority of the patients studied obtained definite relief only when a modified Sippy treatment was instituted.

It was found that the injection of sterile water resulted in slightly more so-called cures than the histidine form of therapy. It must therefore be concluded that histidine not only lacks specificity but is no more beneficial than the injection of sterile water in the therapy of peptic ulcer.

An interesting phenomenon observed was that four of the patients (three of whom received sterile water, and the other histidine) responded remarkably well solely to the parenteral method of therapy. Thus, one must seriously consider the value of psychotherapy in some of the uncomplicated cases.

The ease and rapidity with which a patient responds to therapy depends not alone on the remedy used but also and to an even greater degree on the etiologic and pathologic factors involved. Therefore, individualization of therapy is most essential.

SERODIAGNOSTIC TESTS FOR SYPHILIS
AS PERFORMED BY THIRTY-NINE
STATE LABORATORIES

A COMPARATIVE STUDY

A REPORT OF THE COMMITTEE ON EVALUATION
OF SERODIAGNOSTIC TESTS FOR SYPHILIS

THOMAS PARRAN, MD

Surgeon General U S Public Health Service Chairman

WASHINGTON, D C

WITH H H HAZEN, MD, WASHINGTON, D C, J F MAHONEY, MD, STAPLETON, STATEN ISLAND, N Y, ARTHUR H SANFORD, MD, ROCHESTER, MINN, F E SENEAR, MD, CHICAGO, WALTER M SIMPSON MD, DAYTON, OHIO AND R A VONDERLEHR, MD, WASHINGTON, D C

The results achieved in the first evaluation study of serodiagnostic tests for syphilis in the United States¹ reflected great credit on several of the serologists who had developed original methods. In the first evaluation study a total of 14,238 comparable blood samples and 2,860 comparable spinal fluid samples were tested by thirteen American serologists. It was pointed out in the report of the committee that the actual serologic testing was done under relatively ideal conditions in the laboratories of the originators of the methods and that the results did not necessarily compare with those attained in other laboratories utilizing the same methods.

In the second evaluation study² the committee attempted to meet more closely than was possible in the first evaluation project the conditions encountered in ordinary practice. The efficiency of thirty state, municipal or private laboratories in the performance of serodiagnostic tests for syphilis was measured. The results achieved in many of the state and local laboratories were quite comparable with those attained by the originator of the method employed, who tested comparable specimens as a control measure. It was also obvious that the serologic testing in certain state and local laboratories was highly inefficient.

These observations led the committee to recommend that the United States Public Health Service make an annual comparison of serodiagnostic tests for syphilis done by all state laboratories. It was further recommended that the state laboratories should in turn offer a similar opportunity for comparative testing to the municipal, hospital and private laboratories within each state. It was, however, quite apparent from the results reported by some of the state laboratories that it would be unwise for them to inaugurate a method of control of the local laboratories within their boundaries until they had attained a much higher level of efficiency.

In accordance with the recommendations of the committee, the Surgeon General of the United States Public Health Service invited the health officers of the forty-eight states and the District of Columbia to participate in an evaluation study. The purpose of this project was to determine the efficiency of the performances of the various serodiagnostic tests for syphilis as carried out in those laboratories. The invitation was accepted by the health officers of thirty-nine states. Each health

officer was asked to designate the test or tests the performance of which he desired to have evaluated. The tests specified determined the choice of the methods to be employed as control tests. Thus the laboratories of William A Hinton, Reuben L Kahn, Benjamin S Kline and John A Kolmer were selected and will be referred to in this report as the control laboratories.

The details of the methods utilized for the selection of donors, the collection and distribution of specimens and the tabulation and analysis of reports were similar to those described in connection with the first evaluation study.³ The blood specimens originated from two points, the department of dermatology of the University of Illinois College of Medicine and the department of dermatology and syphilology of the University of Virginia Department of Medicine. Approximately 5 cc of whole blood from each donor was sent to each participating laboratory and to each control laboratory, the special facilities of the postal service being utilized to insure rapid transit and delivery. This necessitated the withdrawal of a single specimen of approximately 250 cc of blood from each donor. Specimen tubes were labeled by code letter and number only. The period of collecting and testing the group of 300 specimens used in this study extended from Nov 1, 1936, to March 15, 1937.

The group of 100 presumably nonsyphilitic donors whose serums were used to determine the specificity (freedom from false positive reactions) of the various tests was, for the most part, made up of medical students between the ages of 20 and 30 years who were apparently free of disease. A control group of this type is, from the standpoint of serologic testing, much more apt to be normal than a group of similar size drawn from hospital patients.

The 200 syphilitic patients used as donors for the purpose of determining the sensitivity (true positive reactions) were selected from the clinics of the department of dermatology and syphilology of the University of Virginia Department of Medicine under the supervision of Dr Dudley C Smith and from the department of dermatology of the University of Illinois College of Medicine under the supervision of Dr F E Senear. Of the donors used in the final tabulation 66 per cent were males and 34 per cent were females. Five per cent of the donors had early secondary infection. The remainder were individuals in whom the disease was of longer standing and who had received varying amounts of treatment.

Of the thirty-nine participating laboratories, twenty-five entered two tests: one complement fixation test and one flocculation test. One laboratory entered two complement fixation tests and one flocculation test. Three participants entered two flocculation tests and one complement fixation test. Two laboratories entered two flocculation tests only. Eight laboratories performed one test, of these five were complement fixation tests and three were flocculation tests. Thus, a total of seventy-four serologic performances was carried out. A total of 11,739 samples was distributed.

In a previous report by the committee¹ the difficulty of finding an adequate method for the rating of doubtful serologic reactions was discussed and cognizance taken of the undoubted value of such observations in treated cases. It is also recognized that doubtful reports on serums of the nonsyphilitic donors used in this study must be looked on as evidence of faulty technic. These factors should, in all fairness, be taken

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Eighth Annual Session of the American Medical Association Atlantic City, N J, June 11, 1937.
1 The Evaluation of Serodiagnostic Tests for Syphilis in the United States. Report of Results. Ven Dis Inform 16: 189 (June) 1935. J A M A 104: 2083 (June 8) 1935.

3 Evaluation of Serodiagnostic Tests for Syphilis. Ven Dis Inform 15: 387 (Dec) 1934. J A M A 103: 1705 (Dec 1) 1934.

into consideration in arriving at a determination of the value of a serologic test in any laboratory. The committee believes that a laboratory that does not report doubtful reactions in nonsyphilitic individuals should receive credit for doubtful reactions in treated cases of syphilis. Conversely, there should be a deduction for

doubtful reactions reported in cases in the control group of presumably nonsyphilitic individuals. Chart 3 shows the added credits and deductions as in the previous evaluation studies the reports of doubtful reactions are given a negative rating in the computation of percent ages in tables 1 and 2.

In tables 1 and 2 and charts 1 and 2 the tests are divided into two main groups, complement fixation and flocculation. An exact classification of procedure was not possible because of the many departures that were taken from the technics described by the originators of the various tests. For example, relatively few participants utilized a technic that was in strict accordance with the Kolmer, Kahn or Kline methods. Divergence from the prescribed technic involved differences in the quantities of the individual components as well as in their proportion, one to another, a wide range of difference in methods for antigen titration and the establishment of the test dose for hemolysin, complement and antigen, and definite modifications in the treatment of the serum and the general mechanism of the tests. In several instances there was adherence to technical procedures that had been either modified or abandoned by the originators.

It is recognized that anticomplementary reactions in some cases may have been provoked by the hazards of transportation. Many of the participating laboratories reported some specimens as hemolyzed or otherwise unfit for testing, these reports do not enter into the final calculations. Therefore it is felt that the classification of anticomplementary results as unsuitable specimens would serve to avoid penalizing the laboratories in which an effort was made to test a hemolyzed or otherwise unsuitable specimen. It should be observed, however, that in certain laboratories a disproportionately high incidence of anticomplementary reactions was reported.

COMMENT AND RECOMMENDATIONS

One of the essential features in any program for the control of syphilis is the general availability of efficient laboratory diagnostic service. Reliable serodiagnostic testing of blood and spinal fluid specimens is a valuable method for the diagnosis of syphilis and for the estimation of the influence of therapeutic agents. While it is not deemed feasible or advisable to restrict the performance of serologic testing to state laboratories, these laboratories should maintain a sufficiently high standard to provide a model of efficiency for the municipal, hospital and private laboratories within the state.

A study of the tables and graphs reveals that some of the state laboratories are qualified neither to perform efficient serodiagnostic service nor to inaugurate any system of state licensure or approval of local laboratories within their respective states.

On the other hand, it is gratifying to observe that in many of the state laboratories the performance of serodiagnostic tests for syphilis is maintained at a highly efficient level. In many of the laboratories participating in this study the results attained compared most favorably with the control tests as carried out by the originators of the methods. It should be observed however that, in some of the laboratories performing more than one test for purposes of evaluation, one of the tests was performed in an efficient manner while the other yielded poor results. In this connection it should be stated that several laboratories entered tests which they did not use as a routine in order to determine their ability to perform such tests efficiently.

Chart 1—Sensitivity (true positive reactions) of blood tests based on the percentage of positive reports in 200 patients with syphilis contrasted with the specificity (freedom from false positive reactions) of blood tests based on the percentage of negative reports in 100 normal presumably nonsyphilitic persons

A study of the technics employed in the serodiagnostic tests for syphilis submitted by the state laboratories reveals that many of them have deviated greatly from the technics described by the originators of the methods. Many of the tests that were designated as Hinton, Kahn, Kline or Kolmer tests by the performers were so modified that it would be an injustice to the originators of the methods to refer to them as such.

The data derived from this investigation indicate that the routine employment of a single serodiagnostic test, although performed by competent workers, is occasionally unreliable. If a single test is used as a routine the laboratory should be prepared and willing to carry out a second test with a different method on request.

The extraordinary disparity in the results of this study indicates the urgent need for the provision of intensive and extensive training of personnel in certain of the laboratories.

The committee makes the following recommendations to state health officers:

1 That provision be made for adequate training of state and local laboratory technicians in the laboratories of the originators of the methods employed in the respective laboratories, and that in the future only thoroughly competent technical personnel be employed. Funds now being made available to the states under the provision of the Social Security Act and allotted for the training of personnel should be utilized for the tuition and stipend of the state and local laboratory technicians.

2 That a system of periodic inspection of state laboratories by

Chart 2—Sensitivity (true positive reactions) of blood tests based on the percentage of positive reports in 200 patients with syphilis contrasted with the specificity (freedom from false positive reactions) of blood tests based on the percentage of negative reports in 100 normal presumably nonsyphilitic persons.

Chart 3—Sensitivity (true positive reactions) and specificity (freedom from false positive reactions) of blood tests for syphilis based on the percentage of positive reports in a group of 200 patients with syphilis and on the percentage of false positive reports in a group of 100 normal presumably nonsyphilitic persons.

thoroughly trained serologists of the United States Public Health Service be inaugurated and made available on the request of state health officers, and that advantage be taken of the system of comparative examination of serodiagnostic tests for syphilis to be extended annually by the United States Public Health Service

3 That the facilities available for special study of serologic methods in the Venereal Disease Research Laboratory of the United States Public Health Service at Stapleton, Staten Island, N Y, be further utilized for the training of personnel from state laboratories

4 That the need is again emphasized for the development by state laboratories of a system of periodic comparative examination of the performance of sero-

unique and efficient manner in which they were carried out. The personnel of the committee indicates again that greater achievements are possible when public health agencies and practicing physicians cooperate in such an undertaking. It was apparent from the results of the second evaluation study that many hospital and private laboratories perform serodiagnostic tests for syphilis in a more efficient manner than certain of our state laboratories. Conversely, some state laboratories performed such tests more efficiently than some of the private and hospital laboratories. I should like to direct attention to the fifth recommendation in the committee's report, namely, "that full advantage be taken of existing local laboratory facilities and that provision be made to approve and subsidize qualified laboratories for the performance of diagnostic services in the control of syphilis." The program of elevating the standards of diagnostic service will not be complete unless hospital and

5 That full advantage be taken of existing local laboratory facilities and that provisions be made to approve and subsidize qualified local laboratories for the performance of diagnostic services in the control of syphilis

ABSTRACT OF DISCUSSION

DR. FREDERICK H. LAMB, Davenport Iowa. This serodiagnostic evaluation study, and the studies that preceded it are symbolic of a definite step forward in the accurate diagnosis and hence in the control of syphilis. No campaign for the eradication of syphilis can succeed unless it is founded on accurate methods of diagnosis. The officers of the United States Public Health Service are to be congratulated not only for sensing the need for such investigations but also for the

private laboratories cooperate in the plan, furthermore the broad scope of the syphilis control program demands the utilization of all qualified local laboratories. It would be disastrous if local laboratories serving hundreds of medium sized and smaller communities should be legislated into extinction. In many communities the clinical pathologist stands as a bulwark between modern and medieval medical practice. Any plan which contemplates the centralization of laboratory diagnostic services in a state laboratory threatens the existence of local laboratories. Moreover, such a plan would deprive the community of the multitudinous services, quite apart from sero-diagnosis, which are so essential to modern, scientific medical practice. The advantages of immediate access to expert assistance in making darkfield examinations and of direct consultation with the clinical pathologists in the interpretation of their reports of diagnostic tests should not be ignored, in fact there is urgent need for the establishment of private or hospital laboratory facilities in scores of communities throughout this

country Such an expansion of diagnostic facilities would greatly elevate the level of medical practice in these areas Any plan for subventionary assistance might well include provision for assistance in the establishment of such local facilities, rather than the further expansion of state laboratory service Therefore, the recommendations of the committee embracing this phase of the problem are most timely and reveal a breadth

but occasionally funds do not permit the state health officer to furnish as high a service as he would like Sometimes lack of quality does creep in and usually the state health officers see the lesser quality in other branches of health work, other than their own When we were invited to cooperate with the U S Public Health Service, it was almost unanimous that we should do so, and the state health officers expected the labora-

of understanding that is highly commendable. The prompt adoption of these recommendations is essential to the success of the venereal disease control program which every right-minded physician earnestly desires.

DR. STANLEY H. OSBORN, Hartford, Conn. This is one place where state health officers are put on the spot in that we were found not to be as good as we thought we were. State health officers try to secure sufficient funds from state governments to operate a reasonably high quality of service,

stories to be shown to be giving a high quality service. Much to our surprise some of them fell below what we had hoped they might show. Again, the dose has had its beneficial results. Two of the men who should be here are not here. Presumably they are home trying to improve the quality of their laboratory service. We are wondering what other things we should aim at in our own departments of health, so that we shall not be exposed before this section as being woefully below what we had hoped we might be. It has taught us that we might also

review the activities of some other divisions or bureaus of our departments, where we think we have reasonably high quality I am sure that if the U S Public Health Service adopts an impartial view of the situation and makes a survey in other activities, as it did in this, it is going to make us look on our own departments with more pride than possibly we are justified in doing today. Those of us who are not in a department of health, but possibly in individual practice, or with individual groups or dispensaries, should also look intimately into their work to see whether perhaps the quality may be improved, before the Public Health Service suggests they should be looked over. It has been a great lesson. Last spring the state health officers met in the city of Washington and there first learned what was coming, and we went home and decided that before we did very many new things we were going to try to improve the quality of the things we were doing.

Clinical Notes, Suggestions and New Instruments

AIR EMBOLISM TO THE SPINAL CORD FOLLOWING ATTEMPTED PNEUMOTHORAX

ABRAHAM WIKLER M.D. JUDAH MARMOR M.D.
AND
ALAN HURST M.D.
NEW YORK

Air embolism to the spinal cord following attempted pneumothorax has, to our knowledge, never previously been described. We believe, therefore, that this case is unique and worthy of report.

REPORT OF CASE

History—A W., a white woman, aged 39, was admitted to the Montefiore Hospital Sept. 23, 1936 with a history of known tuberculosis for the past six months, involving the apex of the left lung. Her complaints on admission were cough, expectoration, and pain in the left shoulder. She was ambulatory, oriented and cooperative, she showed no weakness or limitation of motion of any of her extremities, and the deep reflexes were normal. Sputum examinations were repeatedly positive for tubercle bacilli, and serial roentgenograms of the chest disclosed a progressive fibrocaceous tuberculosis of the left upper lobe.

October 9 an initial left pneumothorax was attempted. The needle was manipulated but no readings could be obtained on the manometer. There was a return of blood through the syringe and the needle was at once withdrawn. Immediately thereafter the patient became pulseless and cyanotic, uttered a peculiar crescendo cry, and did not respond to questions. Her body turned slowly to the right and she groaned incoherently, was incontinent of urine and had a small hemoptysis. The limbs were flaccid, the tendon reflexes in the upper and lower extremities were depressed, and no Babinski or Hoffman sign could be elicited on either side. The eyeballs were deviated upward for a few seconds and then were fixed centrally. The pupils were dilated, regular and equal and reacted well to light. There was a suggestive grasp reflex bilaterally but no sucking reflex. Epinephrine, 5 minims (0.3 cc.), was given hypodermically and the pulse returned, at first slow, later about 90 per minute, regular and of good quality. The respirations gradually increased, and the patient's color improved. After about ten minutes she was able to respond to questions and complained of severe headache, chest pain, nausea, and inability to move her left leg.

When seen the following morning (October 10) the patient was conscious, rational, and oriented in all spheres. She complained of continued weakness of her left lower extremity and of urinary retention. Neurologic examination at this time revealed: 1. Marked weakness and flaccidity of the left lower extremity. 2. Deep reflexes depressed in the left lower extremity, absent abdominals, impaired plantar response on the left with suggestive left Oppenheim and Gordon signs and occasional left Babinski sign. 3. Slight impairment of pain and temperature sensibility in the right lower extremity extending upward to about the eighth dorsal vertebra on the right

and involving also the ninth to eleventh dorsal dermatomes on the left (fig. 1). The sensory impairment in the trunk was more marked than in the extremity. Touch was unimpaired. 4. Impairment in vibratory sensibility in the left lower extremity up to the iliac crest, and slight impairment in position sense in the toes of the left foot.

Twenty-four hours later the patient showed evidence of returning motor power in the left lower extremity. The improvement continued rapidly, so that one week after the initial accident the patient was able to get out of bed and walk about, although with a pronounced limp. The urinary retention had cleared up at the end of twenty-four hours, but some slight difficulty in initiating urination persisted.

Complete neurologic check-up eleven days following the accident (October 20) revealed the following. The mental examination gave entirely normal results. There was a slight limp the left leg being favored. Coordination and skilled acts were normal. There were no abnormal involuntary movements. There was moderate weakness of the left leg as compared to the right. The hamstrings were weaker than the quadriceps; the dorsiflexors of the foot were weaker than the plantar flexors. There was slight hypotonia on the left. No atrophies or fibrillations were noted. The deep reflexes were now increased in both lower extremities but greater on the left than on the right, except for the left ankle jerk, which was slightly decreased. The plantar responses were poor bilaterally, but no pathologic reflexes were elicited except for a questionable left Oppenheim sign. The abdominals were not elicited. The reflexes in the upper extremities were normal.

The sensory observations remained unchanged, except that at this examination the sensory level was several segments higher—sixth dorsal on the right and seventh dorsal on the left. Sensation in the face and upper extremities, including stereognosis, was entirely normal. The cranial nerves were normal. The patient still complained of slight difficulty in initiating urination and defecation.

Subsequent examinations all showed continued and progressive improvement in the patient's neurologic condition.

October 28, nineteen days after the initial incident, the patient still walked with a very slight limp and showed only slight relative weakness of the left leg, although the reflexes were

Fig. 1—Pain and temperature and vibration impairment.

as previously noted. There had been marked regression in the sensory disturbances, the vibratory impairment being demonstrable only in the left ankle and toes, while position sense was normal. The diminution in pain and temperature sensitivity was now very slight, but the patient complained of a subjective sensation of "unpleasantness" when the areas of pain and temperature impairment were touched or stroked. There was still slight retardation in initiating urination and defecation.

November 6, after twenty-eight days, the gait was practically normal. There was very slight relative weakness of the left lower extremity, and the deep reflexes in the left lower extremity

ity were still slightly more active than on the right. No pathologic reflexes could be elicited, but the abdominals were still absent. Vibratory sensibility was now normal, but very slight pain and temperature impairment was still present, especially in the area of the sixth to ninth dorsal segments on the right. Dysesthesia was still present but was less marked.

November 25, forty-five days after the incident, muscle power was equal in the two legs, but the deep reflexes on the

Fig 2—Arteries of a spinal cord segment (modified from Oppenheim, *Textbook of Nervous Diseases for Physicians and Students*). Rdc, dorsal branch of the intercostal artery; Rsa, anterior spinal branch; Rsp, posterior spinal branch.

left were still slightly more active than on the right. The abdominals were not elicited. Dysesthesia was no longer present, but slight pain and temperature impairment was still evident over the sixth to ninth dorsal segments on the right side.

At the time of writing, ten weeks after the accident, there are no abnormal neurologic signs present except for the absent abdominals, and slight hyperreflexia in the left lower extremity.

Laboratory Examinations—Lumbar puncture October 14, five days after the accident, revealed clear, colorless fluid, with no cells, and a negative globulin reaction (Pandy). The initial pressure was 80 mm of water, and the final pressure 40 mm, after removal of 10 cc of fluid. There was no block on jugular compression or abdominal pressure. Total proteins were 34.2 mg per hundred cubic centimeters. The gum mastic curve showed all zeros. Roentgenograms of the spine were negative. Blood counts, blood chemistry, blood platelet count, bleeding and coagulation times were all normal. The blood and spinal fluid Wassermann reactions were negative. Urinalyses were normal. The gastric analysis revealed an achlorhydria.

Summary—In the course of an attempted pneumothorax the patient suddenly went into shock, with loss of consciousness, incontinence, and tonic convulsive movements. On recovering consciousness ten minutes later, she complained of inability to move the left leg. Examination revealed a flaccid paresis of the left lower extremity with pyramidal tract and posterior column disturbances in that extremity, together with spinothalamic impairment in the right lower extremity extending upward to about the eighth thoracic dermatome. There was urinary retention for twenty-four hours. In the course of the next few weeks, recovery took place rapidly and ten weeks after the accident, absent abdominals and slight hyperreflexia in the left lower extremity were the only residual neurologic signs.

COMMENT

The sudden onset of transient shock, unconsciousness and convulsions during an attempted pneumothorax, with puncture of a pulmonary vessel, point indubitably to the occurrence of a cerebral air embolism. The simultaneous onset of paresis of the left lower extremity with level sensory manifestations justifies the conclusion that there was coincidental embolization to the vessels of the spinal cord. The rapid improvement in the neurologic signs is confirmatory evidence in favor of this diagnosis.

The precise localization of the vessels involved and the course taken by the emboli are difficult to state with certainty in the light of our still indefinite knowledge concerning the exact vascular supply of the spinal cord. It would seem in view of the preponderant pyramidal tract and posterior column signs on the left and the spinothalamic signs on the right that we are dealing with a lesion in the distribution of the posterolateral vessels on the left side at the level of the midthoracic cord. The most likely pathway that the embolus or emboli would have to take to involve these vessels would seem to be from the

pulmonary veins into the left side of the heart, thence into the aorta, and out along one of the intercostal arteries on the left side to terminate in branches which communicate with the left posterior spinal artery, in the midthoracic region (fig 2).

In view of the association of the spinal cord lesion with definite, albeit transient evidences of coincidental cerebral embolization, it is of interest to note the work of Herrmann and Vial,¹ who discovered, in experimental embolization of the internal carotid artery in dogs, that those which survived showed diminished or absent reflexes in the fore limbs, with increased reflexes in the hind limbs. Suspecting that emboli were reaching the spinal cord, they injected an aqueous suspension of lycopodium powder into the internal carotid artery and on histologic examination found grains of lycopodium in the vessels of the cervical and upper thoracic cord in thirteen of eighteen cases, the emboli having evidently reached the cord by way of the circle of Willis, down the vertebral arteries, into the anterior and posterior spinal vessels. Whether such a mechanism may have operated in our case we are not prepared to state but it seems less likely than the pathway we have suggested (that is, by way of the intercostal artery).

So far as we have been able to determine, this is the first reported case of air embolism to the spinal cord. Embolization of any kind to the spinal cord is comparatively rare. Most of the reported cases have been in association with subacute bacterial endocarditis,² although a number of cases have also been described of embolic echinococcosis of the arteries of the spinal cord.³

INTESTINAL OBSTRUCTION DUE TO INGESTION OF DRIED PEACH

FRED L. ANDREWS, M.D., AND THOMAS F. WALKER, M.D.
GREAT FALLS, MONT.

A woman, aged 46, was brought to the hospital from the country about 15 miles distant, complaining of pain in the upper part of the abdomen, with nausea and vomiting. The family history was negative. The patient had had the ordinary diseases of childhood. She had three children living and well. Cholecystectomy and appendectomy had been performed in

At right, peach removed from intestine. At left, dried peach shown for comparison.

March 1927. A Colles fracture of the right wrist was sustained in June 1926. All the teeth were extracted several years ago, but no plates were worn.

When first seen at 6 a. m. she was suffering from severe abdominal pain and thought she had "ptomaine poisoning." She had eaten sardines at noon the day before, also the dried half of a peach which, when moistened by the saliva of the month had slipped down her throat. About 7 p. m. the pain began

¹ Herrmann H. and Vial J. *Compt rend Soc de Biol* 116: 523, 1934.

³ Rizzi J. *Rev di pat nerv* 45: 397 (March-April) 1925.

in the upper region of the abdomen, gradually becoming more severe. An enema was taken about midnight with no relief.

In the hospital more enemas were given, without relief. One-fourth grain (0.016 Gm.) of morphine was given hypodermically. The vomiting, which was only occasional at first and consisted of fluids which she had taken, became more frequent, projectile in type and fecal in character. The temperature was 99 F, pulse 136 and leukocyte count 25,000 (polymorphonuclears 94 per cent, lymphocytes 6 per cent). Operative procedure was then decided on.

Under spinal anesthesia a low, median line incision was made. The abdominal cavity was filled with a clear, straw colored fluid, and exploration was begun in the upper part of the abdomen. A sausage shaped mass was palpated in the transumbilical line on the left side in the small intestine, but no attempt was made to determine the distance of the obstruction from the stomach. A longitudinal incision 3 inches in length was made in the intestine and a half peach was removed. The peach showed no signs of digestion and was swollen sufficiently to cause a bulging of the intestine and complete blocking. Closure was made with three layers of gastro-intestinal suture.

The patient was put in Fowler's position. The temperature was 99, pulse 90 and respiration 26. Proctoclysis of 5 per cent dextrose was immediately started. There was no apparent surgical shock. No vomiting occurred after operation and convalescence was uninterrupted until the afternoon of the fourth day, when some saliva ran into the trachea while the patient was asleep, causing a fit of violent coughing, awakening her. During this seizure she felt something "pop" and almost immediately sensed that something had happened.

Under nitrous oxide oxygen anesthesia the wound was opened. The peritoneum and muscle fascia had been torn apart, and bile and fecal material welled into the wound. That portion of the intestine previously operated on was brought into the wound, revealing an opening about one-fourth inch long in the previous incision. This loop of bowel was sutured into the wound with rubber tube drains inserted in both directions, four cigaret drains were also placed in the abdomen. The patient died at 4:30 the following morning. Permission for postmortem was refused.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

BECK-LEE DE LUXE DUO-THERM, MODEL #1207 ACCEPTABLE

Manufacturer: The Beck-Lee Corporation, Chicago

The Beck-Lee De Luxe Duo-Therm, Model #1207, is intended for medical and surgical use. Pads, cuff electrodes and inductance coil attachments are provided for medical applications.

Beck-Lee De Luxe Duo-Therm

Surgical accessories for cutting, desiccation, fulguration and coagulation come as part of the equipment. The machine is housed in a walnut cabinet 21 inches wide, 18 inches deep and 43 inches high. The drawer in the lower part of the cabinet provides storage space for items such as line cord, pads, cable and other accessories. The machine is guaranteed for one year.

Self-rectifying tubes are used in the circuit protected by an input meter, which has on the dial a position to indicate when the tubes are overloaded. The tubes are also protected by a fuse cutout. The wavelength is 15-16 meters for pad and cuff applications and 25-27 meters for the coil technic. The input power is approximately 700 watts under normal operating conditions. Although no method of measuring output power has been adopted officially, the firm rated the output power at 375 watts as determined by the excitation of a lamp load read by a photometer. The temperature rise of the transformer at normal load after a two hour run meets the requirements of the Council.

The firm was asked to present evidence to verify its claims as to the heating ability of the unit. In accordance with the regular procedure of the Council in considering such a device, twelve tests were submitted, six in which the coil technic was used and six with double cuffs. Two vigorous adult male medical students ranging in weight from 150 to 180 pounds were the subjects. A trocar placed in a hard rubber cannula was inserted into the thigh. It was introduced at right angles

Schematic diagram of circuit.

to the thigh and straight down into the depth of the muscular tissue until it was at an approximate depth of 2 inches or until the femur was encountered. The trocar was removed, the rubber cannula being left in situ. Temperature measurements were then taken by means of thermocouples of the hypodermic needle type and introduced through the cannula. The constant junction was immersed in ice enclosed in a quart vacuum bottle. The electromotive force due to the difference in temperature of the junctions was read in millivolts from a Leeds and Northrup portable potentiometer. The thermocouple was calibrated in degrees Fahrenheit against a Bureau of Standards certified thermometer. Initial temperatures were taken and then each student was subjected to a twenty minute application of maximum current intensity consistent with skin comfort. At the end of this period, temperatures were again recorded until the temperatures began to drop. The highest temperature attained was recorded as final temperature in each instance. Oral temperatures were also recorded.

The first six experiments were made with the cuff technic. Two cuffs measuring 3 by 23 inches were wrapped round the thigh equidistant from the cannula, about 7 inches center to center, with one-half inch felt spacing. The next six tests were made with the inductance coil technic. Here three turns of the 12 foot 6 inch cable diameter 1 inch, were wound round the thigh with 1 inch thickness of bath toweling as spacer. There was a space of 2 inches between adjacent turns of the coil. The averages of six tests with the cuff technic and of six tests with the coil technic are given here.

1 Average Temperatures of Six Observations Cuff Technic

Deep Muscle		Oral	
Initial	Final	Initial	Final
100.4	106.5	98.7	99.3

2 Average Temperatures of Six Observations, Coil Technic

Initial	Final	Initial	Final
99.5	107.2	98.3	98.6

The unit was tried out in a clinic acceptable to the Council on Physical Therapy. The clinical results were satisfactory with both technics. The cutting current was also found to be suitable for surgical needs. No claims were made for use of the apparatus in fever therapy. Burns may be produced but can be avoided by the use of ordinary precautions.

In view of the favorable report based on the data obtained by the Council's investigator, using both cuff and coil technics, the Council voted to include the Beck-Lee De Luxe Duo-Therm Model #1207, in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

DIGITALIS (See New and Nonofficial Remedies, 1937, p 180)

The following dosage forms have been accepted

Capsules Digitalis Leaves Sharp & Dohme 1½ grains Each capsule contains one cat unit

Prepared by Sharp & Dohme Inc Philadelphia and Baltimore

Tablets Digitalis Squibb ½ cat unit Each tablet represents ½ cat unit (approximately ¾ grain)

Prepared by E R Squibb & Sons New York

Capsules Powdered Digitalis Squibb 1½ grains Each capsule represents 1011 U S P XI units

Prepared by E R Squibb & Sons New York

PONTOCAINE HYDROCHLORIDE — *p*-butylamino-benzoyl-di-methylaminoethanol hydrochloride — $C_{16}H_{21}NH_2C_6H_4COOCH_2N(CH_3)_2HCl$ The base of pontocaine hydrochloride belongs to the procaine type. It differs from procaine base in that one of the (amino) hydrogens of the aminobenzoate group is replaced by a butyl group, and the two ethyl groups of procaine are replaced by two methyl groups in pontocaine.

Actions and Uses—Pontocaine hydrochloride is a local anesthetic with actions similar to those of procaine hydrochloride, but it is effective when applied to mucous membranes in lower concentrations. It is used for surface anesthesia in the eye, nose and throat, and in spinal anesthesia in which the anesthesia is prolonged.

Dosage—Solution of pontocaine hydrochloride 0.5 per cent is used in the eye, a 2 per cent solution is applied to the nose and throat. The 1 per cent solution is injected for spinal anesthesia for which purpose the dose is from 1 to 2 cc. (containing from 10 to 20 mg of the salt).

Manufactured by the Winthrop Chemical Co. New York N Y U S patent 1889 645 (Nov 29 1932 expires 1949) U S trademark 282 418

Ampules Pontocaine Hydrochloride Solution 1 per cent 2 cc size Each 2 cc of solution contains pontocaine hydrochloride 0.02 Gm sodium chloride 0.0133 Gm and acetone bisulfite 0.004 Gm

Pontocaine Hydrochloride Solution 0.5 per cent Supplied in bottles of one half fluidounce containing 1½ grains of pontocaine hydrochloride (0.5 Gm per hundred cubic centimeters) and ¼ grain of chlorobutanol (0.4 Gm per hundred cubic centimeters)

Pontocaine Hydrochloride Solution 2 per cent Supplied in bottles of one and four fluidounces containing in each fluidounce 9 grains of pontocaine hydrochloride (2 Gm per hundred cubic centimeters) and 1½ grains of chlorobutanol (0.4 Gm per hundred cubic centimeters). The solution is tinted with methylene blue to prevent accidental use for injection.

Pontocaine hydrochloride occurs as a fine white crystalline odorless powder when applied to the tongue it possesses a slightly bitter taste followed by a sense of numbness permanent in the air at ordinary temperature very soluble in water soluble in alcohol insoluble in benzene and ether. Its aqueous solution (1 in 100) is neutral to litmus. Pontocaine hydrochloride melts at 147 to 150 C. From aqueous solutions alkali carbonates and hydroxides precipitate the base as a colorless oil which solidifies when chilled and melts at 41 to 43 C. Dissolve about 0.1 Gm of pontocaine hydrochloride in 5 cc of water add 1 cc diluted nitric acid and 5 cc of silver nitrate solution a white precipitate results filter and wash the precipitate is soluble in ammonia water.

Dissolve about 0.2 Gm of pontocaine hydrochloride in 20 cc of water divide into two portions to one portion add 0.2 cc of diluted hydrochloric acid 0.2 cc of a 10 per cent solution of sodium nitrite and gradually add to a solution of 0.2 Gm of hetanaphthol in 10 cc of a 10 per cent sodium hydroxide solution a white precipitate occurs (distinction from the anesthetics responding to the diazo reaction) saturate the other portion with hydrogen sulfide no coloration or precipitation results (salts of heavy metals). Dissolve about 0.1 Gm of pontocaine hydrochloride in 1 cc of sulfuric acid the solution is colorless (readily carbonizable substances).

Dry about 0.5 Gm of pontocaine hydrochloride accurately weighed at 100 C for six hours the loss in weight does not exceed 10 per cent. Incinerate about 0.5 Gm of pontocaine hydrochloride accurately weighed the residue is not more than 0.1 per cent. Transfer about 0.3 Gm of pontocaine hydrochloride accurately weighed to a 500 cc Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists third edition page 20 chapter 2 paragraph 22 the percentage of nitrogen corresponds to not less than 9.1 nor more than 9.5 when calculated to the dried substance. Transfer about 0.3 Gm of pontocaine hydrochloride accurately weighed to a suitable Squibb separatory funnel add 25 cc of water followed by the addition of 2 cc of sodium hydroxide solution extract with seven successive portions of ether using 35 cc 30 cc 25 cc 20 cc 15 cc 10 cc and 10 cc respectively wash the combined ethereal solution with 15 cc of water filter through a pledget of cotton evaporate to a thick oil in a stream of warm air and dry to constant weight over sulfuric acid in a partially exhausted desiccator the

weight of *p*-butylaminobenzoyl dimethylaminoethanol obtained corresponds to not less than 87.3 per cent nor more than 88.3 per cent when calculated to the dried substance. Transfer the alkaline aqueous portion from the immiscible solvent extraction to a 400 cc beaker and place on the steam bath for 3 hours add 100 cc of water followed by the addition of 10 cc of nitric acid and 25 cc of silver nitrate solution subsequently boil with continuous stirring and allow to cool in a dark place. Collect the precipitate of silver chloride on a Gooch crucible wash with diluted nitric acid and water followed by alcohol and ether finally dry to constant weight at 105 C the amount of hydrogen chloride calculated from the silver chloride found corresponds to not less than 12.0 per cent nor more than 12.3 per cent when calculated to the dried substance.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C BING Secretary

LARSEN'S 'FRESHLIKE' STRAINED CEREAL

Manufacturer—The Larsen Company, Green Bay, Wis

Description—A pureed cereal preparation made from processed whole wheat, whole milk, barley, soy beans, wheat germ and salt, requiring only warming for serving and specially intended for infant feeding.

Manufacture—Formula proportions of the dry ingredients are mixed in stainless steel kettles, whole milk is added and the mixture is mixed and heated until the starch grains swell and disintegrate. The mixture is strained twice, mechanically filled into enamel-lined cans and sealed. All of these steps are performed under vacuum. Cans are processed at 116 C for one hour and cooled in water.

Analysis (submitted by manufacturer) — Moisture 80.5%, total solids 19.5%, ash 1.2%, fat (ether extract) 1.8%, protein (N × 6.25) 5.0%, crude fiber 0.09%, carbohydrates other than crude fiber (by difference) 11.4%, calcium (Ca) 0.106%, phosphorus (P) 0.330%, iron (Fe) 0.0013%, ratio phosphorus to calcium 3.11, ratio carbohydrate to protein 2.28.

Calories—0.82 per gram, 23 per ounce

Vitamins—The method of preparation appears to be adequate to retain in high degree the vitamins normally present in the ingredients.

RANNEY'S FINEST BRAND STRAINED UNSEASONED PRODUCTS (PEAS, GREEN BEANS, CARROTS, BEETS, SPINACH, CELERY, TOMATOES, APPLES, PRUNES, APRICOTS, AND VEGETABLES WITH CEREAL AND BEEF BROTH)

Distributor—Ranney-Davis Mercantile Company, Arkansas City, Kan

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively strained peas, spinach, carrots, beets, green beans, celery, tomatoes, prunes, apples, apricots and vegetables with cereal and beef broth, prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL Aug 26, 1933, p 675, Aug 12, 1933, p 525, Aug 19, 1933, p 605, July 8, 1933, p 125, July 29, 1933, p 366, Sept 2, 1933, p 779, July 1, 1933, p 35, July 22, 1933, p 282, Aug 10, 1935, p 437, July 4 1936, p 38, July 22, 1933, p 283).

SCHAAF'S 'FAVORED FOR FLAVOR' EVAPORATED MILK

Distributor—Frank Schaaf Company, Milwaukee

Packer—Page Milk Company, Merrill, Wis

Description—Unsweetened, sterilized evaporated milk, the same as Page Brand Evaporated Milk (THE JOURNAL, May 30, 1931 p 1872).

ERYTHROCYTES IN PERNICIOUS ANEMIA

Notwithstanding the important advances that have been made during the past few years in the treatment of pernicious anemia and in the partial elucidation of the chemical nature of the material effective in the treatment of this disease, the fundamental cause of the anemia remains unsolved. Whipple¹ believes that the underlying cause may be a lack of material needed for the formation of the stroma of erythrocytes and therefore that the cells formed are of subnormal structural strength. Some insight into this question may be acquired when the chemical constitution and the mode of action of the antianemic principle are determined. Another approach to the problem, however, is the study of the chemical composition and the physical structure of erythrocytes from patients with typical pernicious anemia. Possibly the disease is associated with changes in the red cell or, indeed, the anemia may be a result of chemical abnormalities of the cell itself.

A series of studies have been conducted at the Research Laboratory of the Children's Fund of Michigan² to obtain accurate information regarding the chemical composition of erythrocytes from normal subjects and from patients with various types of hematologic disorders. The results recently reported on erythrocytes from patients with pernicious anemia, both in relapse and in remission induced by liver extract, are particularly significant. During relapse some increases in the cation and anion content of the cells were observed, which were due chiefly to the presence of increased amounts of potassium and of hemoglobin. The most striking changes from normal, however, were those in the lipid components of the erythrocytes. There were significant increases in the amounts of cholesterol esters and decreases in the amounts of phospholipid and free cholesterol. Induced

remission of the disease by liver extract therapy was accompanied by a prompt return of the values to normal.

An interpretation of these data is difficult at the present time. There is some evidence³ that physiologic activity in a tissue or organ is associated with an increased content of phospholipid and of free cholesterol, whereas lowered activity, degeneration and retrogression are accompanied by a decreased content of these lipids and an increase in the amount of neutral fat and cholesterol esters present. If this general relationship applies to erythrocytes from patients with pernicious anemia, the foregoing results indicate that these cells are in a state of lowered activity or that they are degenerating and retrogressing.

Further work on this important problem is needed. As stated by the Michigan workers, chemical analyses of the isolated stroma of erythrocytes may yield further and more revealing information.

THE NATIONAL CANCER INSTITUTE

A bill¹ establishing a National Cancer Institute as a division of the United States Public Health Service has passed both houses of Congress. It will become a law when signed by the President. The bill creates a National Cancer Advisory Council and enlarges the functions and resources of the Public Health Service with respect to the study and treatment of cancer. To house the proposed institute, the Secretary of the Treasury is empowered to acquire suitable land in or near the District of Columbia and the appropriation of \$750,000 for the erection and equipment of buildings is authorized. An annual appropriation of \$700,000 is authorized for maintenance and operation. The Secretary of the Treasury is authorized, too, to accept gifts and bequests to further the work of the institute. All this, moreover, is not to replace but to supplement such authority and appropriations relating to the study of the prevention, diagnosis and treatment of cancer as the Public Health Service and other agencies of the United States already have. The responsibility for the operation of the institute is divided between the National Advisory Cancer Council, the Surgeon General of the Public Health Service and the Secretary of the Treasury.

The National Advisory Cancer Council is to consist of the Surgeon General, ex officio, as chairman, and six members appointed by him with the approval of the Secretary of the Treasury from leading medical and scientific authorities outstanding in the study, diagnosis or treatment of cancer in the United States. Each appointive member is to be paid at the rate of \$25 a

2 Williams H. H., Erickson Betty N., Bernstein Samuel, Hummel Frances C. and MacV. Icie G. The Lipid and Mineral Distribution of the Serum and Erythrocytes in Pernicious Anemia. J. Biol. Chem. 118: 599 (May) 1937.

3 Bloor W. R. and Snider Ruth H. Phospholipid Content and Activity in Muscle. J. Biol. Chem. 107: 459 (Nov.) 1934. Boyd E. M. The Lipid Content of the Jelly of Wharton. J. Biol. Chem. 111: 61 (Nov.) 1935.

day for such tune as he devotes to his official duties. The council is to certify to the Surgeon General, for investigation, experiment and study, programs relating to the cause, prevention, diagnosis and treatment of cancer deemed by it worthy of such action. It is to collect and, with the approval of the Surgeon General, make available to physicians and other scientists and to the public the results of studies throughout the world pertaining to cancer. The council is to examine applications for grants-in-aid for research projects relating to cancer and to certify to the Surgeon General, who is authorized to make such grants, such projects as show promise of worth-while results. Tenders to the Secretary of the Treasury of gifts that are limited by conditions named by the would be donors are to be appraised by the council, which is to certify to the secretary for acceptance such gifts as the council believes will further the purposes of the act.

The Surgeon General of the Public Health Service is authorized to provide facilities where training and instruction concerning cancer will be given to qualified persons, and provision is made for paying such persons while they are being so educated and trained. In addition, research fellowships may be established by the Surgeon General for investigators from any part of the world, and the assistance of experts from the United States or elsewhere in matters pertaining to cancer may be employed. Commissioned officers in the Public Health Service may be appointed in such numbers as may be necessary to aid in carrying out the provisions of the act. The Surgeon General may purchase radium and make it available for purposes of the act, and he may, subject to such conditions as the Secretary of the Treasury shall prescribe, lend radium to institutions for the study of the cause, prevention and method of diagnosis or treatment of cancer or solely for the treatment of cancer. Grants-in-aid may be made by the Surgeon General to universities, hospitals, laboratories and other institutions, or to individuals, for research projects relating to cancer certified by the National Cancer Advisory Council as worthy of such grants.

The Secretary of the Treasury is authorized to accept any unconditional gifts or bequests to be used for furthering the purposes of the act and to accept any conditional gifts for that purpose if acceptance is recommended by the Surgeon General and the council.

The act will become effective thirty days after its approval by the President, but in accordance with congressional practice it carries no appropriation and may have to wait until an appropriation is made before it becomes operative.

It is to be hoped that the use of the abundant funds proposed in this act, following so closely on the gift of \$10,000,000 by a private donor to Yale University for cancer research, will hasten the day when the cause of cancer is known and prevention and cure are available.

INFLUENCE OF MINERAL CONSTITUENTS OF BONE ON OSSIFICATION

Although there has been much research on the problem of ossification and its characteristic features, some of the most important aspects of this process remain obscure. Chief among these are the mechanism by which calcium is deposited in the bone matrix and the nature of the immediate stimulus that leads to the formation of bone in a given location. The suggestions offered to answer some of these perplexing problems of ossification have in general taken one of two directions. One theory of ossification may be termed humoral or chemical, and Leriche and Policard,¹ who have championed this hypothesis, postulate "a local calcific surcharge as the determinant of osteogenesis in a suitable fibrous medium." These authors emphasize the rarefaction of bone at the extremities of the fragments that occurs after a fracture. They believe that this liberates calcium in the region and leads to a local excess of calcium, this being an important factor in the union of fractures. The other theory of ossification considers that the process is cellular, or vital, the bone being formed as a product of specific cells (osteoblasts) which, under proper conditions, have the capacity of laying down bone. The two theories agree that bone deposition can occur only in the presence of an adequate supply of calcium and of other bone constituents. The divergence of the two theories lies primarily in the question whether the stimulus for ossification is of chemical (humoral) or cellular (vital) origin.

The experimental approach to the evaluation of these two theories of ossification is obviously easier in the case of the chemical hypothesis than in the study of the cellular or vital theory. Chemical alterations in the environment of the bone structure are much simpler to secure experimentally than are conditions that are optimal for the differentiation of primitive connective tissue into osteoblasts. As a consequence a number of reports have been made regarding the effect of experimentally produced local salt depots on the process of ossification. The evidence has been for the most part inconclusive because of the inability of investigators to control accurately all the variables, such as the influence exerted by the operative procedure necessary for the introduction of the salt. Also it is frequently observed that repair occurs as rapidly in the control as in the experimental fracture.

Recently Bisgard² has described experiments designed to eliminate controversial technique and to assess accurately the influence of an excessive local supply of calcium on ossification. At the same time a study was made to determine whether bone, in the form of partially viable bone, boiled bone or bone ash, might alter the repair process. Autogenous transplants of certain tissues were made to the anterior chamber of each eye of a large number of rabbits and several dogs. In most instances

1 Leriche R and Policard A. *The Normal and Pathological Physiology of Bone* translated by Sherwood Moore and J A Key. St Louis C V Mosby Company 1928

2 Bisgard J D. Ossification Arch Surg 33 926 (Dec) 1936

the grafts promptly became attached to the iris, from which they became vascularized. After this had occurred, aqueous suspensions of either bone salts or bone ash were injected into the anterior chamber of approximately half the eyes. The transplants in the eyes in which salts were not injected served as controls. After varying periods the animals were killed and the grafts were recovered and studied microscopically. The synthetic salts of bone, calcium carbonate, calcium phosphate and magnesium phosphate had no influence on osteogenesis or ossification. In great concentration and in the presence of tissue not in itself osteogenic but regarded as ossifiable, these salts failed to give rise to the formation of bone and in the presence of osteogenic tissue they did not appear to alter the normal process of ossification. On the other hand, bone, regardless of its viability, had a favorable influence on ossification. This was true also of bone ash. The conclusion is drawn, therefore, that bone ash possesses some factor favorable to ossification that is not present in the artificial salt mixture. It may be inferred from these observations that calcium as it exists in bone may be present in a physiochemical or structural form more suitable for use in the process of ossification.

The experiments of Bisgard are of further interest when viewed in the light of recent evidence indicating that the breaking strength of bones appears to be more closely correlated with organic pattern, as reflected in the size of the bone, than with the proportion of inorganic salts.³ It seems possible that observations of this type, supplemented by other data, may serve to bring into closer harmony the two principal theories of ossification and to lay equal emphasis on the importance of each. The process may require both a proper chemical stimulus in the form of a correct balance and concentration of the inorganic salts of bone and the vital activity of the osteoblasts for laying down the correct organic pattern into which these salts may be deposited.

FEDERAL REGIMENTATION OF PHYSICIANS AND HOSPITALS

Senator J. Hamilton Lewis of Illinois introduced in the Senate, July 28, a joint resolution¹ "To provide medical aid for the needy and the stricken with illness who are unable because of poverty to provide treatment and hospitalization, also to establish all licensed medical practitioners as civil officers of National Government." The resolution, which was referred to the Committee on Finance, would in effect relieve the states of all responsibility and expense for the medical and hospital care of the indigent sick and injured within their respective borders and would bring the medical profession and all hospitals under federal control so far as might be necessary for the purposes of medical and hospital relief. Senator Lewis proposes to organize the medical profession and the hospitals of the United

States to care for and treat, at the expense of the federal government and in accordance with rules and regulations promulgated by the Social Security Board all infirm, sick and destitute persons in need of care and treatment and unable to provide it. The resolution outlines the framework of a federal civilian medical corps such as was described by Senator Lewis in his recent address² before the House of Delegates of the American Medical Association at Atlantic City.

Senator Lewis's resolution proposes that for the purposes therein set forth every physician who practices medicine in the United States be a civil officer of the United States government. In effect, every such physician is to be drafted into a federal medical relief service whether he desires it or not, without regard to his citizenship, age, infirmity, education, training or experience. His term of office is to be for life, regardless of good or bad behavior, for no provision is made for suspension or removal from office for any cause, or for resignation. The utmost freedom in choice of physicians is proposed, any person in need of medical treatment and unable to pay for it is to be empowered, if the resolution is enacted, to demand treatment by any physician and the physician is to be bound to respond. A physician having under treatment an impoverished patient in need of hospital care would have authority, in event of the enactment of the resolution, to order his patient's hospitalization by any hospital, and a hospital, on receipt of such an order, would have to receive and care for the patient in a manner best adapted to effect his recovery, so far as the facilities of the hospital would permit.

Bills for medical and hospital services would be sent to the Social Security Board and would be paid if the board found them reasonable and just. The resolution is silent as to the payment of bills in cases in which the physician or the hospital on the one hand and the Social Security Board on the other cannot agree as to the reasonableness and justice of the amount charged.

Any physician and any hospital official or employee who refuses to render the service required of him is to be liable, if this resolution becomes a law, to a fine of not more than \$1,000 or to imprisonment for not more than three months, or both. Similar penalties are proposed for any physician or hospital official or employee making exorbitant charges, for any physician or hospital charging a patient anything in addition to the amount charged the federal government for the same services, and for any person who, in order to obtain medical and hospital services at the government's expense, falsely represents that he is destitute and unable to pay for medical treatment.

The resolution proposes that the Social Security Board be authorized to make such rules and regulations as are necessary to carry out the terms of the resolution. It is silent as to the official organization necessary to

³ Clarke, Miriam F. Bassin, A. L. and Smith, A. H. *Am J Physiol* 115: 556 (May) 1936.
¹ S. J. Res. 188.

² Address of Hon. J. Hamilton Lewis, J. A. M. A. 105: 11 (June 26) 1937.

provide proper supervision and control over physicians, hospitals and patients coming within the terms of the resolution. It makes no provision for the services of dentists or of nurses or for medical and surgical supplies, nor does it provide for any of the other needs of the destitute sick. The resolution contains no indication of the estimated cost of the proposed service and is silent as to the taxes to be levied by the federal government to raise the money necessary to pay that cost.

This joint resolution must pass the Senate and the House of Representatives and be approved by the President before it becomes a law. Introduced at this late date, there is little likelihood that it will be enacted before the adjournment of the present session. Apparently it has been introduced for the purpose of getting the views of its author before Congress and the public.

Current Comment

SERODIAGNOSTIC TESTS FOR SYPHILIS IN STATE LABORATORIES

Elsewhere in this issue (page 425) appears the Report of the Committee on Evaluation of Serodiagnostic Tests for Syphilis. It is a comparative study of efficiency of the performance of serodiagnostic tests for syphilis in thirty-nine state laboratories. Four private laboratories were used as controls. A study of the tables and graphs obtained from the sixty-nine serologic performances on each specimen of blood submitted revealed the fact that some of the state laboratories are qualified neither to perform efficient diagnostic service nor to inaugurate any system of licensure involving approval of local laboratories within their respective states. In many states, however, the efficiency of the performance of the tests was maintained at a high level. It was also evident that the routine employment of a single serodiagnostic test, even though performed by competent workers, is occasionally unreliable. The recommendations of the committee should receive immediate study. It was advised that provision be made for adequate training of state and local laboratory technicians in the laboratories of the originators of the methods employed and that in the future only thoroughly competent technical personnel be employed. A system of periodic inspection of state laboratories by thoroughly trained serologists of the United States Public Health Service should be devised and made available. The facilities for the special study of serologic methods in the Venereal Disease Research Laboratory of the United States Public Health Service at Staten Island should be utilized to a greater extent. Periodic comparative examination of the performance of serodiagnostic tests is desirable. Finally, the committee advised that full advantage be taken of existing local laboratory facilities and that provisions be made to approve and subsidize qualified local laboratories for the performance of diagnostic services in the control of syphilis.

Abbott, Tuscaloosa, "Urinary Infections in Infancy and Childhood".

ARKANSAS

Personal—Dr. Benjamin C. Middleton, Texarkana, has been appointed health officer of Miller County.—Dr. Fount Richardson, Fayetteville, has been appointed physician to the University of Arkansas.

Polio-myelitis in Pulaski County—Nine cases of polio-myelitis were reported to be under treatment at the Little Rock City Hospital and four deaths had occurred, newspapers reported July 15. In Pulaski County, outside of Little Rock, six patients were still under quarantine July 16 and three had recovered with partial paralysis.

Society News—At a meeting of the Tri-County Clinical Society, Prescott, June 24, the speakers were Drs. John Harry Hayes, Little Rock, on diagnosis of hyperthyroidism, Bryce Cummins, Little Rock, anesthesia, Robert Paul Hughes, Prescott, acute conditions of the abdomen, and Francis W. Regnier, Prescott, metastatic sarcoma of the lung.—The Randolph-Lawrence County Medical Society was addressed at Smithville, June 8 by Drs. Henry B. Hull, Mammoth Springs, on dysentery, Cleo C. Ball, Ravenden, rheumatoid arthritis, and Edwin Dunn, D.D.S., Imboden, pyorrhea.—At a meeting of the Sebastian County Medical Society, June 8, Drs. Joseph F. Shuffield, Little Rock, discussed "Treatment of Nonunion of Fractures and Special Treatment of Fracture of the Patella", and Ewell I. Thompson, Little Rock, "Treatment and Management of Syphilis".

CALIFORNIA

Mussel Quarantine—A quarantine of all mussels from the ocean shore of California extending from the southern boundary of Los Angeles County north to the California-Oregon boundary, with the exception of San Francisco Bay, has been established for the period June 1-September 30.

Society News—Dr. Maurice B. Visscher, professor and head of the department of physiologic chemistry, University of Minnesota School of Medicine, Minneapolis, addressed the Hollywood Academy of Medicine, July 15, on "The Old and the New in the Story of Digitalis".—Dr. Norman Bethune, Montreal, discussed "Experiences in Spanish War Hospitals" at a special meeting of the San Francisco County Medical Society, July 27. At a general meeting, August 10, Dr. Clarence A. Mills, James T. Heady, professor of experimental medicine, University of Cincinnati College of Medicine, will speak on "Health and Disease Aspects of Environmental Effects: The Specific Relation of Air Conditioning to Health".—At a meeting of the San Joaquin County Medical Society in Lodi, June 3, Dr. Salvatore P. Lucia, San Francisco, read a paper entitled "Ancient Greek Physicians".—Dr. Frank H. Krusen, Rochester, Minn., addressed the Santa Barbara County Medical Society, Santa Barbara, June 14, on fever therapy.

COLORADO

New Division of Tuberculosis—Dr. Fred A. Forney, Woodmen, has been appointed director of the new division of tuberculosis of the state department of welfare, with headquarters in Denver. Under a recent law a sum was appropriated to provide care for indigent tuberculous patients in private tuberculosis sanatoriums. This law was passed in lieu of a proposed law to establish a state tuberculosis sanatorium. It was reported. It was supported by the state medical society in view of the large number of tuberculosis sanatoriums in Colorado which have been operating far below their capacity for many years. Under the new plan the state welfare board will hospitalize indigent persons in several of these institutions at a set per diem rate. Dr. Forney graduated at the University Medical College of Kansas City in 1906. A member of the

staff of the Modern Woodmen Sanatorium Woodmen, for many years, he has been medical director and superintendent since last January. He was formerly county physician of Reno County, Kansas, and at one time president of the Kansas State Health Officers' Association.

FLORIDA

District Meeting—The first annual meeting of the Northwest District of the Florida Medical Association was held in Apalachicola July 15 with the following program:

- Dr. Edward Jelks Jacksonville, president Florida Medical Association, Appendicitis
- Dr. Ernest F. Wahl Thomasville Ga. Uses and Abuses of the Electrocardiograph
- Dr. Frederick C. Moor Tallahassee, Collapse Therapy in the Treatment of Pulmonary Tuberculosis
- Dr. Otis W. Britt Chattahoochee Ala. Ray Diagnosis
- Dr. Mark F. Boyd Tallahassee Malaria

The program was arranged by the officers of the Leon-Gadsden-Liberty-Wakulla-Jefferson Counties Medical Society.

ILLINOIS

Memorial to a "Country Doctor"—The dedication of a huge boulder to the memory of Dr. Stewart Craig Thomson took place on the lawn of Byron school, August 1. Dr. Thomson was killed in an automobile accident Oct. 30, 1931, near Byron. The boulder weighs nearly a ton and is inscribed with words commemorating the life and service of Dr. Thomson who exemplified the typical "country doctor," newspapers reported August 1 would have been his sixty-seventh birthday.

New District Health Units—Nine full time district health units have recently been set up in Illinois, the first of twenty to be financed jointly by the state department of public health and the U. S. Public Health Service under the social security act. Following are the names of the newly appointed superintendents and the counties in their districts:

- Dr. Wellington C. Van Wormer Homewood Cook DuPage and Will counties
- Dr. James A. Poling Freeport Stephenson Carroll Jo Daviess Lee and Ogle counties
- Dr. Carl A. Peterson Moline Bureau Henry Mercer Rock Island and Whiteside counties
- Dr. Sandor Horwitz Peoria Marshall Peoria Putnam Stark Tazewell and Woodford counties
- Dr. Loran E. Orr Greenville Cass Logan Mason Menard and Sangamon counties
- Dr. Nettie A. M. Dorris Paris Champaign Coles Douglas Edgar and Vermilion counties
- Dr. Joseph L. Bryan Xenia Clay Edwards Jefferson Marion Wabash and Wayne counties
- Dr. Roland R. Cross Dahlgren Franklin Gallatin Hamilton Saline White and Williamson counties
- Dr. Lewis S. Barger Golconda Alexander Hardin Johnson Massac Pope Pulaski and Union counties

Chicago

The Capps Prize—The Institute of Medicine of Chicago offers the Joseph A. Capps Prize of \$500 for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. Competition is open to graduates of Chicago medical schools who completed their internship in 1935 or who completed one year of laboratory work in 1936. The winner of the prize will be expected to present the results of his investigation before the institute at some meeting in 1938, the time to be designated later. Manuscripts must be submitted to the secretary of the institute, 86 East Randolph Street, Chicago, not later than December 31.

IOWA

Personal—Dr. Harry P. Smith, professor of pathology, State University of Iowa College of Medicine, Iowa City, has received a grant of \$10,000 from the John and Mary R. Markle Foundation for research on blood clotting and the bleeding tendency.

Society News—Dr. Philip A. Daly, Chicago, addressed the Black Hawk County Medical Society in Waterloo June 15 on "The Thyroid Gland in Relation to Pregnancy." At a meeting of the Johnson County Medical Society in Iowa City June 2, the speakers were Drs. Harry R. Jenkinson on "Poisoning from Shoe Dye" and William F. Boiler "Rocky Mountain Spotted Fever." Dr. Henry G. Decker, Des Moines, discussed "The Scope of Neurologic Surgery," before the Madison County Medical Society in St. Charles June 14. At a meeting of the Ringgold County Medical Society in Mount Ayr June 29, Drs. Charles L. Seaman, Mount Ayr, spoke on "Ulcerative Colitis," Elbert J. Watson, Diagonal, pneumonia, and James W. Hill, Mount Ayr, ectopic gestation.

KANSAS

New Health Officers—The following new health officers are announced in the state medical journal: Drs. Leroy S. Ott, Leoti, Wichita County; Otis H. True, Bird City, Cheyenne County; George R. Lee, Yates Center, Woodson County; and Edwin M. Ireland, Coats, Pratt County.

Temporary Injunction to Osteopaths—Federal Judge Richard J. Hopkins granted the osteopaths of Kansas a temporary injunction June 29, in an action filed to compel H. D. Baker, collector of internal revenue in Kansas, to issue them narcotic permits. A recent ruling of the attorney general of the state concurred in by the U. S. Narcotic Division stated that osteopaths in Kansas were not legally entitled to administer narcotics. Permanent ruling in the matter probably depends on the outcome of two test cases, now pending in Kansas courts, concerning osteopaths' rights under the state osteopathy practice act, it is said.

LOUISIANA

Dr. Walton Goes to Mississippi—Robert P. Walton, Ph.D., assistant professor of pharmacology, Tulane University of Louisiana School of Medicine, New Orleans, has been appointed professor and head of the department of pharmacology, University of Mississippi School of Medicine, University, Miss. He will take over the position September 1. It is reported Dr. Walton has been identified with Tulane since 1929, shortly after he received his degree of doctor of philosophy at Columbia University, New York.

New Professors at Louisiana Graduate School—Dr. Walter E. Levy, assistant professor of clinical obstetrics, Tulane University of Louisiana School of Medicine, New Orleans, and professor of obstetrics at the graduate school, has resigned to become professor and head of the department of obstetrics at the Louisiana State University Graduate School of Medicine. Dr. Levy graduated at Tulane in 1917. Dr. William D. Phillips, formerly on the staff at the graduate school of Tulane, has been appointed professor and head of the department of gynecology at Louisiana State and Dr. John F. Dick, also a former member of the staff of Tulane, has been named professor of gynecology and associate director of the department. Dr. Phillips graduated at Tulane in 1909 and Dr. Dick in 1912.

MASSACHUSETTS

Another Million Volt X-Ray Unit—A new million volt x-ray machine was recently installed in the Collis P. Huntington Memorial Hospital, Harvard University Medical School, Boston, for the treatment of patients with cancer.

Officers of Medical Board Re-elected—Dr. Francis R. Mahony, Lowell, was reelected chairman of the Massachusetts Board of Registration in Medicine at its recent annual meeting, and Dr. Stephen Rusmore, Boston, was reelected secretary.

Acting Commissioner of Mental Diseases—Dr. Clifford T. Perkins, Brookline, a member of the state department of mental diseases since 1935, has been appointed assistant commissioner and acting head of the department during the absence of Dr. David L. Williams, commissioner. Dr. Perkins is a graduate of Boston University School of Medicine, 1936.

Personal—Dr. Marshall L. Alling, Lowell, has been reappointed medical examiner of the fifth Middlesex district. Dr. Edward W. Wilder, head of the Willis F. Pierce Memorial Hospital, Madurai, India, who has been active in missionary work in India, was recently awarded the silver Kaiser Medal, a decoration given by the Indian government for distinguished service in social or educational work, according to the *Boston Traveler*. He is a native of Boston. Otto Kraver, of the faculty of the American University of Beirut, Syria, formerly of the University of Düsseldorf and the University of Berlin, has been appointed associate professor of pharmacology, Harvard University Medical School, Boston, for five years beginning next September, according to *Science*.

MINNESOTA

Cardiac Hospital Project—A cardiac clinic for treatment of children susceptible to the development of chronic heart disease has been maintained since December 1935 as part of the Lymanhurst Health Center, Minneapolis, by the Works Progress Administration under the auspices of the city division of health. Since the project was begun, 135 children suffering with incipient heart disease have been treated. The undertaking includes research activities in the laboratory, connected with the clinic and the compilation of records to determine causes and proper correctional procedure for treatment of these cases. The hospital occupies the top floor of the health center. There are two wards of twenty beds each, a study room, children's

dining room, library, enclosed porch for play diet kitchen electrocardiograph room a two bed isolation ward and an administrative suite. The patients range between 4 and 14 years of age are selected from the children attending the heart clinic at Lymanhurst and are admitted through the Minneapolis Public Relief Admitting Service for General Hospital. School nurses and physicians refer children who complain of symptoms suggesting rheumatic infection or who are found to have evidence of cardiac disease during their regular school physical examination. On admission, seventy-seven were found to have potential heart disease, with active rheumatic infection but as yet no signs of heart involvement. The patients are carefully studied through x-ray, electrocardiograph and laboratory examinations. They receive care for an average period of three months and are kept strictly on bed rest until all signs of activity have disappeared. In almost every instance the active rheumatic infection has become quiescent and their general condition has improved under the supervised treatment it is reported. School work is provided from kindergarten to the tenth grade. Follow-up work is carried on after the child is discharged. Dr Francis E Harrington city health commissioner, directs the project, which is supervised by Dr Morse J Shapiro.

MISSOURI

Dr Davis's Slayer Sentenced to Hang—Robert Kenyon was found guilty July 23 of slaying Dr James C B Davis Willow Springs, and was sentenced to be hanged September 2. Dr Davis aged 67 was summoned into the country January 29 on a fictitious call to attend a patient. The Davis family became alarmed after receiving two ransom demands for \$5,000. His bullet-torn body was found in a thicket a week later it was reported.

Hospital News—The construction of a new \$1,080,000 marine hospital in Kirkwood has been approved. Work has begun on a new psychopathic hospital, adjacent to the City Hospital, St. Louis, to be named in honor of the late Dr Malcolm A Bliss. It will be five stories high with accommodations for 186 patients. The Park Lane Memorial Hospital St. Louis has recently been opened. It has a capacity of sixty beds. Dr Frank J Smith is the director.

Health Coordinator Named—Sen James S Rollins Columbia, representing the tenth Missouri district in the state senate has been selected by the federal government to act as coordinator between the state board of health and the state department of education in the public health education program which is to be incorporated into Missouri's schools newspapers report. Senator Rollins' salary will be paid with federal funds it was stated, and his office will be located in the headquarters offices of the state department of health.

MONTANA

State Medical Election—Dr James C MacGregor, Great Falls was chosen president elect of the Montana State Medical Association at the annual meeting in Great Falls July 13-14 and Dr William P Smith Columbus was installed as president. Dr Ernest D Hitchcock, Great Falls, was elected vice president and Dr Thomas L Hawkins, Helena, secretary.

NEW YORK

Cancer Commission Appointed—Members of a commission authorized by the recent session of the legislature to survey the prevalence of cancer in the state and facilities for treatment were recently announced. Six members of the legislature were appointed by officials of that body and the following physicians were named by Governor Lehman: Drs Edward S Godfrey Jr, Albany state health commissioner; James Ewing director of cancer research, Memorial Hospital for the Treatment of Cancer and Allied Diseases New York; and Floyd S Winslow, Rochester, immediate past president of the Medical Society of the State of New York. The commission has an appropriation of \$15,000 and will report to the 1938 legislature.

Medical Minstrels—Alumni of the Syracuse University College of Medicine presented "Medical Minstrels of 1937" after the annual alumni dinner June 1 at the Hotel Syracuse. Nearly 100 physicians took part in the show which included an old fashioned minstrel show musical presentations dancing and a skit called "The Bedside Manner" written by Dr William E Pelow. Among special numbers were solos by Drs Raymond D Markle Waterbury Conn Francis R Irving and Henry Walden Retan dancing by Drs Harry C Myron Jr and Thomas E Walsh a two piano act by Dr John C M Brust and Mr Henry Lupes and a quartet by Drs Raymond

Markle, Charles D Reid Gordon D Hoople and Thomas F Laurie. Dr George L Wright was interlocutor for the minstrel show.

New York City

Three Health Centers Dedicated—Three district health centers for the New York City Department of Health have been dedicated since the first one of the group, that in East Harlem described in THE JOURNAL July 17 page 215. They are the Mott Haven center 349 East One Hundred and Fortieth Street dedicated June 29 the Lower West Side center 303 Ninth Avenue, July 13 and the Greenpoint center 151 Maujer Street Brooklyn July 27.

Changes in Faculty at Long Island College—A department of preventive medicine and community health has been established at Long Island College of Medicine, Brooklyn, under the direction of Dr Alfred E Shipley, professor of clinical preventive medicine and community health, it was recently announced. The new department will conduct most of its work in the Red Hook-Gowanus Health Center through an affiliation recently effected with the New York City Department of Health for training of medical students in public health work. Dr Tasker Howard, professor of clinical medicine has been promoted to be professor of medicine and physician-in-chief to Long Island College Hospital, to succeed the late Dr Luther F Warren. Dr Robert L Moorhead has been appointed professor of clinical otolaryngology to succeed Dr Charles Waldo Stickle, now emeritus professor, and Dr Fedor L Senger, assistant clinical professor of urology has succeeded Dr J Sturdivant Read now professor emeritus. The appointment of Dr Jean A Curran as dean of the school was announced in THE JOURNAL, March 13, page 891.

The Health Exhibits at the New York World's Fair—Plans for a million dollar medical and health exhibit at the New York World's Fair in 1939 were announced recently by Grover A Whalen president of the fair and Louis I Dublin PhD, chairman of the executive committee of the fair's advisory committee on medicine and public health. A design for the building which may be called "A World of Health" has been completed. About 10,000 feet of floor space will be used for a display that "will indicate to man in an entirely new and dramatic manner what to do so that he may take utmost advantage of the store of scientific knowledge now available to insure his health and that of his family." The health building will occupy a triangular plot of land on the "Theme Plaza" will be in the form of a V and will cost about \$425,000. In the center will be the Hall of Man, an oval chamber in which will be a heroic figure of man revealing by transparency the internal anatomy the circulatory digestive and nervous systems and the glands of internal secretion. Here also will be numerous models explaining man's physiology. To the left of the Hall of Man will be the Hall of Medical Sciences, in which will be displays showing various diseases and the means available for protection against them. There will also be a Hall of Public Health and a Theater of Hygiene where lectures will be presented by medical and health authorities. Many models will be so arranged that they can be manipulated by the visitors to show such motions as the articulation of joints, flow of blood and the processes of digestion. In addition to these displays sponsored by the fair the building will have about 70,000 feet of floor space to be "financed by a group of selected sponsors."

PENNSYLVANIA

Personal—Dr Roy W Goshorn Bellwood has been appointed superintendent of the Blair County Hospital for Mental Diseases Hollidaysburg to succeed the late Dr Henry J Sommer. Dr Carl E Ervin chief of the medical department of George F Geisinger Memorial Hospital Danville has resigned to enter private practice in Harrisburg.

Society News—Dr William L Long Philadelphia, addressed the Lehigh County Medical Society, Allentown July 13 on "The Use of Some New Drugs Affecting the Sympathetic and Parasympathetic Nervous System." At a meeting of the Venango County Medical Society in Oil City June 18 a symposium on cancer was presented by Drs Cecil H Hodgkinson Oil City, Paul E Cunningham and Franklin P Phillips Franklin and John C Wilkins and Joseph T Danzer Oil City. Dr Chevalier L Jackson Philadelphia addressed the Schuylkill County Medical Society, Shenandoah June 22 on "Indications for Bronchoscopy." Dr Arvin E Trollinger of the staff of the Veterans' Administration Facility at Coatesville addressed the Chester County Medical Society at the hospital July 20 on insulin treatment of dementia praecox.

Philadelphia

Promotions at Temple—Among promotions recently announced by Temple University School of Medicine were the following

Dr Louis Cohen to be assistant professor of medicine
Dr Morton J Oppenheimer assistant professor of physiology
Drs Wilbur E Burnett and James Norman Coombs assistant professors of surgery

Police Surgeon Attacked—Dr Joseph T Freeman, a police surgeon received a fractured jaw and lacerations of the head in an attack by a group of men who hailed him to have a supposedly injured companion taken to a hospital according to a newspaper report. Dr Freeman lifted the injured man into the rumble seat of his car and when he told others of the group he was unable to take them all he was beaten severely. One man when arrested confessed in court to the attack.

Personal—Dr David Riesman emeritus professor of clinical medicine and professor of the history of medicine, University of Pennsylvania School of Medicine, received an honorary doctorate of laws at the June commencement of the University of Wisconsin—Dr Basil R Beltran has been appointed chief surgeon and medical director of the eastern state penitentiary succeeding the late Dr Mitchell P Warmuth—Dr Rose Hirschler has been appointed professor of dermatology at the Woman's Medical College of Pennsylvania. Dr Hirschler graduated from the college in 1899—Dr Elise Whitlock-Rose recently received a gold medal the annual achievement award of the San Domingo Council Knights of Columbus in recognition of her work at the Notre Dame des Malades Clinic which she founded for the care of indigent women and children

Pittsburgh

Personal—Dr Paul Titus was recently decorated by the Hungarian government with the Commander Cross of the Hungarian Order of Merit in recognition of his work in obstetrics. Dr Titus is secretary of the American Board of Obstetrics and Gynecology

SOUTH CAROLINA

Society News—Drs Benjamin C Bishop and William Thomas Brockman addressed the Greenville County Medical Society, Greenville, July 5, on "Hemorrhoids—When to Treat and When to Operate" and "Nervous Indigestion and What Can Be Done About It" respectively—Dr Keitt Hane Smith, Greenville, addressed the Oconee County Medical Society, June 3, on treatment of urinary infections by mandelic acid—At a meeting of the Fifth District Medical Society recently in Chester the speakers included Drs Stephen W Davis, Charlotte, N C on "Physical Therapy" and Verling K Hart, Charlotte "Bronchoscopy in the Diagnosis of Intrathoracic Conditions"—Dr Isaac A Bigger, Richmond Va, addressed the York County Medical Society, Rock Hill at a special meeting July 8, on "Surgery of the Pericardium and Heart"—Among speakers at the annual meeting of the Eastern Carolina Medical Association at Myrtle Beach July 16 were Drs James Heyward Gibbes, Columbia, "Heart Pains", James C McLeod, Florence, "Management of Acute Injuries", Samuel F Ravenel, Greensboro, N C "The Nervous Child", Joseph Decherd Guess, Greenville "Problems in the Conduct of Labor," and Elbert L Persons, Durham, N C, "An Everyday Approach to Skin Disease"

TENNESSEE

Promotions at Vanderbilt—Promotions recently announced by Vanderbilt University School of Medicine Nashville included the following

Dr Edna H Tompkins to be associate professor of anatomy
Morton F Mason, Ph D assistant professor of biochemistry
Dr Herbert C Francis assistant professor of preventive medicine and public health
Roy J Morton, M S assistant professor of preventive medicine and public health

TEXAS

Society News—At a meeting of the Gray-Wheeler Counties Medical Society in Wheeler recently, the speakers included Drs Joel Zeigler Shamrock on "Blood Transfusions", Elmer W Jones, Wellington "Unilateral Polycystic Kidney" and Harold E Nicholson, Wheeler, "Review of the Vitamins, Their Sources and Uses"—Drs Henry A Petersen and John T Moore, Houston addressed the Hardin-Tyler Counties Medical Society, June 8 on "Trend Toward Socialized Medicine" and "Fundamentals in Treatment of Cancer of the Breast" respectively—A symposium on tuberculosis was presented before the McLennan County Medical Society, Waco, June 8 by Drs Frederick W Hoehn, Walter C Bidelsbach, Wesley W Klatt

and James W Hale, all of Waco—The Dallas Obstetrical Society was recently organized with the following officers: Drs Wayne T Robinson, chairman, Watt W Winn, vice chairman, and Herbert F Laramore, secretary—Dr Joseph H Dorman, Dallas, was elected president of the Texas Railway Surgeons' Association and Dr Ross B Trigg, Fort Worth, reelected secretary at a meeting in Fort Worth in May

WEST VIRGINIA

Personal—Dr and Mrs Cyrus Haymond Maxwell Morgantown, celebrated their golden wedding anniversary July 6 with a reception at their home. Dr Maxwell was born in 1863 and graduated from Gross Medical College, Denver, in 1893 after having been a teacher in Arkansas, Oregon, California and West Virginia. He has practiced in Morgantown about thirty-five years. In 1930-1931 he was president of the West Virginia Medical Association

GENERAL

Oregon License Lost—Dr Roger W Debusk, Madison, Wis., reports that he has lost a license granted to him in January 1935 by the Oregon State Board of Medical Examiners. The number of the license is 2792

Council to Coordinate Birth Control Activities—A central council to coordinate the activities of the American Birth Control League and the Birth Control Clinical Research Bureau has recently been formed. Mrs Margaret Sanger is chairman of the new council which will be known as the Birth Control Council of America and Henry Pratt Fairchild, Ph D, New York, is vice chairman. Members representing the American Birth Control League are Mrs Louis deB Moore, Drs Frederick C Holden and Eric M Matsner, New York, and Clarence C Little, Sc D, Bar Harbor, Maine, alternate. Those representing the Birth Control Clinical Research Bureau are Dr Hannah M Stone, Rabbi Sidney E Goldstein and Dr Ira S Wile, with Dr Abraham Stone as alternate. All are of New York.

Internal Use of Opium Preparations Defined—The use for aural, nasal, ocular, rectal, urethral or vaginal purposes of preparations containing opium or any of its salts or derivatives is not external use, but is internal use and is to be regulated accordingly under a recent amendment by the Acting Commissioner of Narcotics of Article 103 of Narcotic Regulations No 5, as amended. The manufacture, compounding, dispensing, and use for any of the purposes named of any preparation containing opium or any of its salts or derivatives in excess of the quantities allowed for so-called exempt preparations by the Harrison Narcotic Act as amended must conform in every respect with the law and regulations governing the manufacture, compounding, dispensing and use of the same drugs for other internal uses.

Film Shows Radium Refining Processes—A film celebrating the completion of production of the first ounce of radium at the El Dorado Refinery, Port Hope, Ont., from ore taken out of the radium deposits discovered in 1930 near Great Bear Lake in northwestern Canada, was completed and shown during the week of July 8. According to an announcement, the film shows the refining process, which now produces radium crystals at the rate of 35 Gm a month. It also shows ceremonies celebrating the production of the first ounce, attended by Sir Frederick Banting, Toronto, Gilbert LaBine, the mining engineer who discovered the radium deposits and Dr Herbert C Bruce, lieutenant governor of Ontario. Since the discovery of the Canadian ore the price of radium previously controlled by the Belgian monopoly that owns the supply in the Belgian Congo has dropped from \$75,000 to \$25,000 a gram, it is said. It is estimated that the total supply of radium in the world is about 600 Gm of which about 225 Gm is believed to be in the United States.

Society News—Dr George Miller MacKee, New York, was elected president of the Society for Investigative Dermatology at the organization meeting in Atlantic City in June. Dr Joseph V Klauder, Philadelphia, was made vice president. Dr Samuel W Becker, Chicago, secretary and Dr Joseph Gardner Hopkins, New York, treasurer. The society was organized for the purpose of presenting a forum for those interested in the investigative field of dermatology including not only dermatologists but investigators in allied fields who are working with the skin and its appendages—Dr William P Healy, New York, was chosen president elect of the American Radium Society at the annual meeting in Atlantic City in June and Dr Edward H Skinner, Kansas City, Mo., was installed as president. Other officers elected were Dr Lawrence R. Taussig, San Francisco, and Maurice Lenz, New

York, vice presidents and Frederick W. O'Brien Boston secretary—The Central Association of Obstetricians and Gynecologists will hold its ninth annual meeting October 14-16 at the Hotel Adolphus Dallas Texas

FOREIGN

Exhibition of Summer Camps—A National Exhibition of Summer Camps and Youth Welfare was opened in Rome June 20 and will continue to September 30. It is announced that the exhibition is designed to give a complete idea of what is being done in Italy to foster the moral and physical health of the younger generation.

The Marking of Thermometers—A law has recently been adopted in Czechoslovakia requiring that fever thermometers be "hall marked" according to a report from the U. S. Department of Commerce. Henceforth only mercury type thermometers with the official Czechoslovak "hall mark" can be sold and used by the local medical profession.

Prize for Medical Reports—The Académie Duchenne de Boulogne Paris, is offering a prize of 10,000 francs for reports of work in the medical sciences by an independent worker of French nationality. The prize will be awarded the first Thursday in December and reports must be sent by October 1 to the Secretariat of the Académie Centre Marcelin Berthelot 28 Bis rue Saint-Dominique Paris 7.

Society News—The ninth International Congress of Psychotherapists will be held at Copenhagen October 2-4. Further information can be obtained from Prof. Poul Bjerre 4 Engelbrektsgratan Stockholm. The "Congres International du Tourisme du Thermalisme et du Climatisme" will have a meeting in Paris at the exposition grounds October 14-17 at which Dr. Guy Hinsdale White Sulphur Springs W. Va. will represent the United States. The International Spa Congress will be held in Budapest October 7-14. The Royal Medical Society of Budapest will celebrate its centenary, October 6-8.

International Medical Week in Switzerland—The *Swiss Journal of Medicine* has organized the third International Medical Week to be held at Interlaken from August 29 to September 4. One day will be spent at Berne under the auspices of the medical faculty of the University of Berne. Among the lecturers listed on the program are:

Dr. Hugh W. Cairns, London Results of Treatment of Intracranial Tumors
Dr. Otto Loewi, Graz Austria Chemical Transmission of Nerve Impulses
Dr. Hans Spemann, Freiburg Germany New Observations on the Manner of Animal Development
Dr. Hans C. Hagedorn, Copenhagen Denmark Advances in Insulin Therapy
Dr. Leopold Lichtwitz, New York Disturbances in Regulation of Carbohydrate Metabolism

For information address the *Journal Suisse de Médecine* Klosterberg 27 Basel.

CORRECTION

Forty-Two Years a Secretary—The *JOURNAL*, June 12, page 2045, reported that Dr. Thomas Douglass Ozark Ark. had been secretary of the Franklin County Medical Society continuously for forty-three years with the exception of the year 1922, when the late Dr. Edward W. Blackburn Ozark held the office. Dr. Blackburn was vice president and not secretary, as recorded in the news item.

Government Services

Changes in Public Health Service

The following appointments and commissions have been announced in the U. S. Public Health Service:

Dr. Richard S. Bolten assistant surgeon reserve corps Lewisburg Pa.
Dr. Leo D. O'Hane assistant surgeon reserve corps Leavenworth Kan.
Dr. William Walcott passed assistant surgeon reserve corps Washington D. C.
Dr. Jeff T. Anderson as passed assistant surgeon reserve corps Fort Leavenworth
Dr. Wightman R. Duke assistant surgeon reserve corps at New Orleans
Dr. Dale C. Cramer as a sistant surgeon reserve corps San Francisco
Dr. Martin A. Ruona assistant surgeon Springfield Mo.
Dr. John A. Lewis Jr. as assistant surgeon reserve corps U. S. Marine Hospital Cleveland
Dr. Jack L. James assistant surgeon reserve corps Leavenworth
Dr. Wixom S. Sibley assistant surgeon reserve corps U. S. Marine Hospital Cleveland

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 10, 1937

The Promotion of Clinical Research

The Medical Research Council is inviting applications for a second series of studentships and fellowships intended to encourage young British medical graduates of special ability and original mind toward becoming investigators in branches of medical science. The field includes investigation into disease in patients with experimental work of an immediately relevant kind. Six postgraduate studentships are offered for graduates who have already held house appointments. Each selected student will receive \$1,000 per annum in a period not exceeding twelve months for personal maintenance while undertaking such approved courses of study as may be best calculated to advance his training in methods of research. This study may include modern languages and such advanced physiologic, pathologic and special clinical work, under recognized teachers, as may form a suitable preliminary to research work to be undertaken later. The approved course may not include studies of which the purpose is to enable the student to pass further examinations.

The council is also offering four research fellowships for candidates of similar qualifications who already have had some experience in research methods. Each will be tenable for one year at \$1,250 per annum and will be renewable in approved instances at the rate of \$1,500 for a second year. They are intended as probationary appointments for research in clinical science or experimental pathology. Research expenses may be provided in addition to the stipend.

The National Physique

Improvement of the national physique has become a foremost political problem. In the House of Lords Earl Stanhope, president of the Board of Education moved the second reading of the physical training and recreation bill, which has already passed through the Commons. He said that the demand for increased opportunities for physical training and fitness, particularly among the youth, was a striking phenomenon of the present day. Viscount Dawson (president of the Royal College of Physicians) stated that the bill was necessary in the interest not only of the present generation but of future generations. In the past, nature secured a fit race by killing off the unfit. Now we were gradually undoing nature's efforts by our greater sense of humanity toward the weak. He did not doubt that this was the right policy, but it increased the necessity to create fitness. A national college of physical training was the pivot of the scheme. There students would learn technique and men who were going to take up physical education as a whole time job could be trained. Organizers and leaders of voluntary organizations could receive a shorter and less strenuous training.

Turning to the need for adequate nutrition Viscount Dawson said that the distribution of undernutrition was patchy. In the London elementary schools the children were for the most part well nourished, even in the poorest districts. On the other hand in the distressed areas, where unemployment was rife, undernutrition could be found. But it had to be remembered that many heads of households had never been taught how to choose food and spend their earnings to good advantage. Further, few knew how to cook. One of the best investments that the government could make would be to provide traveling vans to go about the country, from which lectures could be given on the choice and cooking of food.

Replying for the government Earl Stanhope agreed that undernutrition was due more to lack of education than to lack

of money. In Czechoslovakia the improvement of physique among all classes, and particularly among the working classes, by voluntary methods was remarkable. This was due more to physical training than to better nutrition.

The Measurement of Daylight in Rooms

Some 2,000 scientists and industrialists visited the National Physical Laboratory to see the progress that had been made in practical scientific research during the past year. They were received by Sir William Bragg, president of the Royal Society and chairman of the general board of the laboratory. In the photometry department has been perfected a factor meter which automatically measures the amount of daylight penetrating into rooms. By means of two photo-electric cells the intensity of light in a room is compared with that of the sky vault. It is thus possible to tell at a glance how good or how bad is the lighting of a room. The daylight factor is beginning to be used extensively by the authorities in deciding on slum clearance schemes, for the instrument has the advantage of not being subject to errors of judgment on the part of the user. The minimum daylight factor considered suitable for working conditions is 0.2 per cent. In some of the Glasgow slums the factor is as low as 0.003 per cent.

Another apparatus is used for testing the sensitivity of the eye to colored light, with special reference to colored street lights. It has been suggested that the eye may work most efficiently by the light of some particular color. To test this theory a cinema film of a street scene was prepared in which various objects appear and disappear. This is projected on a screen by means of lights of different colors. The time taken by observers to notice the various objects is measured for the different colors.

Some Improvement in Road Accidents

The National "Safety First" Association is able to announce some improvement in the number of road accidents, owing partly to its efforts, though the toll taken by the roads is still appalling. Until 1930 the number of road casualties increased in almost the same proportion as the number of automobiles. But compared with 1930 the 1936 statistics showed an increase of 20 per cent in the number of automobiles, while there was a decrease of 18 per cent in the number of pedestrians killed. These figures are valuable because for the first time in the comparison of road casualties the increase in the number of automobiles is taken into account. In the case of children the improvement is even more marked, for there has been a reduction each year since 1930 in the number of their fatalities, and this in 1936 was 25 per cent below the level of that year. But there is an increase of 69 per cent in the number of cyclists killed, which is attributed to the increased popularity of cycling. It is more than twenty years since the movement for greater safety on the roads was begun and the original safety code recommended is now the official highway code. But the accident problem is so great that there is still much work for the association, though more and more of its work is being officially undertaken.

Provident Nursing Scheme for London

A scheme by which in London the working class can have services of nurses in their homes by the provident payment of one cent a week has been brought forward. Speaking at an inaugural meeting, Lord Horder, chairman of the council, said that the reason so small a subscription was adequate was that it could be collected in bulk at the place of employment. Home nursing was the only health service which still remained uncovered by the provident principle. London was lagging behind many of our large cities where the system had been established and proved successful. What are called "district nurses" are already provided by charity for the same purpose, but it has proved necessary to ask for payment from patients of what they can afford.

PARIS

(From Our Regular Correspondent)

July 3, 1937

Benign Spontaneous Pneumothorax

At the May 21 meeting of the Societe medicale des hopitaux, two unusual cases were reported by Prof. E. Rist, one of the leading tuberculosis specialists in Paris. The first patient, a youth of 17, first noticed a severe thoracic pain without much dyspnea. A few days later a hemorrhagic pleural exudate was found at the base of the right side of the thorax. Fifteen days after the exploratory puncture, all the accompanying fever and signs of the exudate had disappeared. Radioscopy revealed only a slight diminution of diaphragmatic movements and a normal pulmonary shadow. After an interval of thirty-three months, during which all examinations had been negative, radioscopy revealed a complete right pneumothorax and a slight pleural exudate. This observation cleared up the origin of the previous hemorrhagic exudate as being due to a benign spontaneous thorax with hemorrhage. The second patient, a medical student, gave the history of having had a serofibrinous pleurisy. Six years later a sudden severe pain in the chest accompanied by dyspnea was noted. The following day a complete total right pneumothorax was found, which disappeared rapidly, followed by apparently complete recovery. In this case there had been an old tuberculous pleurisy followed by a spontaneous benign pneumothorax on the opposite side. In the discussion, Dr. Cathala reported a case in which bleeding from the right nipple in a young girl was followed by a benign spontaneous pneumothorax of the same side. The question arose whether there was any relation between the two in the form of rupture of tiny angiomas. Dr. Jacob reported a case of spontaneous benign pneumothorax accompanied by syncope and a large hemorrhagic pleural exudate. There was also a history of a severe hemoptysis, of short duration, followed by apparent cure. Radioscopy had been negative during this attack.

Nonoperative Treatment of Pulmonary Tuberculosis

At the May 21 meeting of the Societe medicale des hopitaux a paper was read by Leon-Kindberg and Weiller on the division of bandlike adhesions and associated intrapleural chrysotherapy rapidly efficacious artificial pneumothorax. They stated that the two chief obstacles in securing results from an artificial pneumothorax, are, first, band or bridle-like adhesions between the lung and the parietal pleura and, second, the irretractability of the pulmonary stump (collapsed lung). To overcome the first of these the Jacobus technic has been of great aid, but it is often difficult to carry out. Leon-Kindberg has called attention to the good results obtained by injecting gold salts intrapleurally, at first alone and, later, combined with intrapleural procedures. These two methods are now regularly employed at the Beaujon Hospital. The results were illustrated by lantern slides. By applying this method in half of the cases in Leon-Kindberg's service, its efficacy could be compared with cases in the other half of the service, not so treated. The importance of the combined gold salts therapy and intrapleural division of bands is especially evident when collapse therapy as a whole is considered. In the discussion, Professor Rist agreed with the authors as to the efficacy of early pneumothorax treatment. Four fifths of the cases thus treated have shown the benefit of early pneumothorax therapy within six months and half of these in less than three months. About one fifth of the patients have shown evidence of its efficacy later than six months after beginning the early pneumothorax treatment. This late appearance of a beneficial result may be due to faulty technic in giving the pneumothorax treatment, improvement occurring later, when a more correct technic is used. Improvement follows division of bandlike adhesions, and the benefits of the pneumothorax treatment manifest themselves only after the establishment of an artificial pleural cavity.

Icterohemorrhagic Spirochetosis

Two papers on icterohemorrhagic spirochetosis were read at the May 7 meeting of the *Société médicale des hôpitaux*. The first paper reported three cases in coal miners and was presented by Rimbaud, Janbon and Bordenave of Montpellier, in southern France. Apparently the disease raged in a mild endemic form, fifteen miners having shown symptoms during August 1936. Four of the fifteen died. In the first of these three cases, the chief clinical features were a febrile syndrome with myalgia and injection of the conjunctivae, marked icterus, a blood urea of 110 mg per hundred cubic centimeters, and a meningeal reaction. The second patient presented a febrile syndrome with myalgia, a subicteric hue, a less marked meningeal reaction (14 lymphocytes), a blood urea of 150 mg per hundred cubic centimeters, which did not appear until the twenty-eighth day, and positive Martin-Pettit serodiagnostic reactions. In the third case, in addition to the febrile and myalgic syndrome, purpura and phrenic neuralgia were noted. The blood urea rose to 170 mg per hundred cubic centimeters and the spinal fluid contained seventy-four mixed cells. The serum reactions of Pettit and Martin were positive. Relapse of symptoms occurred twice during the period of observation. Attention was especially drawn by the authors to the high blood urea in the three cases, as well as to the incidence of this form of infection in miners. This raises the question as to whether icterohemorrhagic spirochetosis should be considered as a professional, i. e., industrial, disease. In the 1936 law it is so regarded, but its possible occurrence is limited to those who work in the sewers of large cities, like Paris. Hence the authors maintain that in view of their observations it is necessary to include miners in those who can benefit from such a law.

In a second communication by the same authors, two cases of the disease are reported in which icterus was absent. Such a typical form of icterohemorrhagic spirochetosis, without hemorrhages or icterus, are difficult to recognize clinically. The first patient was a dish washer in a restaurant situated on the bank of a little river in southern France. The onset was sudden, in the form of chills followed by profuse perspiration, headache, dysphagia, and generalized pain in the muscles and joints. The admitting diagnosis was influenza, bronchitis and pharyngitis. During the patient's stay in the hospital the constant absence of icterus was noted, but the urine examination revealed the presence of bile salts and pigments. The temperature varied from 103 to 104 F. The blood urea was normal but there were symptoms resembling those of meningitis. The serum reactions of Pettit and Martin were positive. The second patient was a girl, aged 16 years. The onset and initial syndrome were quite analogous to those of the other patient. There were, however, a morbilliform erythema, a blood urea of 100 mg per hundred cubic centimeters, no icterus or bile salts or pigments in the urine, and a secondary meningeal syndrome with 216 leukocytes of mixed formula in the fluid obtained by spinal puncture. The serum reactions of Pettit and Martin were strongly positive.

Echinococcus of the Liver

At the June 2 meeting of the *Académie de chirurgie* a contribution to the study of echinococcus infection in France was made by Dr F. Deve, an internist. He reported that surgeons of Besançon had observed seventeen cases, to which Wilmoth added another, making a total of eighteen cases, seventeen of which were from the departments of France adjacent to western Switzerland. All eighteen patients had been born and raised in that portion of France. In addition to these three other isolated cases had been reported from northern and central France. The clinical picture is that of a chronic icterus with hepatomegaly and splenomegaly and the striking anomaly that

not only are the general condition and appetite good but there is no accompanying rise of temperature. In the majority of cases the complement deviation and intradermal tests with the hydatid liquid are positive. Any doubt regarding the diagnosis is cleared up by biopsy at operation. Surgeons should be familiar with the special appearance of the lesions, as was shown in sections of tissue presented by Deve at the meeting. There are no ordinary cystic single or multilocular earmarks of the disease. It forms a tumor-like, more or less colloid, mass, which explains why it is often diagnosed as a cancer of the liver. The essential feature is the presence of firm, sclerotic tissue, literally riddled by many cavities the size of a pinhead. Near the central zone the mass shows evidence of softening and necrosis, leaving a turbid bile-stained liquid lying in a tiny cavity in which neither hydatid cysts nor membranes are ever found. At its periphery one finds constant infiltration, with necrosis, of the fibrous sheaths of the bile ducts as far as the hilus of the liver, thus greatly resembling the picture of a malignant growth. The jaundice is the result of extrinsic pressure on the bile ducts at the hilus and the intracanalicular invasion of the bile passages by the echinococcus formations. When the abdomen is opened the gross appearance of the liver strongly resembles that of a cancer, but the nodules present special pathognomonic features. They are harder than those of a cancer, more boardlike, cartilaginous, and often accompanied by a thick sclerotic hepatitis of chondroid aspect. A biopsy soon reveals the nonmalignant character of the lesions.

Noncancerous Consolidations in Pulmonary Cancer

To make an early diagnosis of cancer of the lung, one must always bear in mind that the neoplasm begins in the bronchi, according to Ameuille and Fauvet, who read a paper at the May 14 meeting of the *Société médicale des hôpitaux*. When evidence of consolidation of the lung itself is found, this means that the neoplasm is already at an advanced stage, the primary bronchial cancer having invaded the surrounding lung tissue. However, the special point of the paper was to call attention to the existence of consolidation of a noncancerous character. Two cases were described. In the first patient, the diagnosis of a cancer, well localized in a left sided bronchus, was made with the aid of iodized poppy-seed oil. It was accompanied by complete absence of respiratory sounds in the middle third of the left lung. There was also evidence of consolidation in the right middle lobe. At necropsy the diagnosis of the left bronchial cancer was verified but the area in the right lung proved to be a focus of gangrene and pneumonia not directly related in any way to the lesion on the left side. In primary bronchial cancer one frequently sees areas of atelectasis around the cancerous areas in the lung. This collapse of the lung may be quite extensive and is the direct result of the blocking of the corresponding bronchus by the neoplasm. Such atelectases may appear suddenly and the clinical picture is like that of acute massive collapse of the lung. A diagnosis of cancer of the left lower main bronchus was made in the second case, which had been under observation for ten months. The first clinical sign had been a sudden hemoptysis, in a man 50 years of age. Bronchography with the aid of iodized oil and examination of biopsy specimens obtained by endoscopy showed a cancer of the bronchi of the right median and lower lobes. Following a slight hemoptysis in November 1936, radiography revealed a total collapse of the lower fourth of the right lung and a less complete similar condition of the lower portion of the right upper lobe. A similar collapse occurred four months later, even though the bronchi were not obstructed. In both of these two attacks of collapse the normal lung shadow reappeared soon afterward showing that such transient atelectasis was not of cancerous nature and that the bronchi were

not obstructed. These two cases show that one must keep in mind the occurrence of such concomitant pulmonary collapse attacks in patients who have a bronchial cancer, in order to be able to estimate accurately the degree of invasion of the lung tissue in cases of pulmonary cancer.

Undulant Fever of Bovine Origin

One of the first cases of undulant fever of bovine origin in France was reported by Professor Ledoux of Besançon in 1928, and since then numerous cases have been observed in all parts of France. Between 1928 and 1932, twenty-five cases were found in three departments of that portion of France which is close to Switzerland. In a paper read at the May 25 meeting of the Académie de médecine Professor Ledoux and his associates reported seventy-two additional cases from the same three departments. In the majority of the seventy-two recent cases it was not difficult to trace the manner in which contamination took place, but in several there had been no contact with infected animals and no contaminated milk ingested. Nearly always, undulant fever of bovine origin is the result of lack of washing of the hands on the part of those who come in contact with infected animals. Undulant fever as seen in eastern France is of a milder type, as a rule, than that of southern France. However, severe infections with bone and liver complications have been seen. There is a likelihood that the disease will assume a more severe character in eastern France in the future, with the rapid increase in importation of sheep into this part of the country. The cattle will soon become contaminated by contact with infected sheep, and hence a strict control of all animals brought from other departments has become imperative.

June 19, 1937

The Sickness Insurance Societies

By recent regulations, the duties of the supervisory medical consultants in the sick insurance, a group which already exert an influential role, are substantially expanded. This measure has long been contemplated. The status of the medical consultant is explicitly defined as that of a sociological-medical adviser to the insurance societies. One of the aims of this medical service is a harmonious accord between the conflicting interests of the individual insured person, the insured as a group and the societies themselves. Accordingly, the consultant becomes a sort of medical welfare worker and adviser to the individual insured who stand in need of help but he is legally prevented from making any unauthorized demands on or misusing the societies' funds. There should be the closest cooperation between the consultant and the insurance society. Since the physician is not yet regarded as an employee of the society, there exists no status of superior or subordinate between him and the society's officials. Each party is supposed to repose the fullest confidence in the other and to keep the other mutually informed by verbal communication. If an insurance official disagrees with the opinion or proposal of a medical consultant, he should inform the latter in person if possible of his dissension.

The consultant will render his professional opinion only in conjunction with his regular duties and according to his best medical judgment with due consideration of the legal requirements of the sick insurance. He must submit a detailed written report of all follow-up or verifactory examinations. The consultant must observe professional secrecy even after his services to the sick insurance have ceased, but this secrecy does not apply in his dealings with the insurance societies, the governmental health officials and so on, on the contrary, the consultant must supply the societies with all relevant data.

The duties of a supervisory medical consultant may be outlined as follows: 1 Follow-up examinations of persons inca-

pacitated for work, judgment of the nature and extent of the disability and recommendation of special tests indicated. The consultant selects the patients for whom follow ups are necessary from among persons claiming sick benefits and in the order designated by the society. In general, the insurance society obtains a case record from the attending physician, in urgent cases a report may be made by telephone. The attending physician is invited to participate in the follow up examination. The attending physician is to be informed of the consultant's opinion and of any relevant observations with regard to diagnosis and recommended treatment. All statements by the consultant must be so phrased that the reputation of the attending physician will be safeguarded before the insured patient. The consultant must take especial care that his relations with attending physicians and with the League of Insurance Physicians of Germany remain free from needless friction and he must endeavor to cultivate cooperation. 2 Follow-up examinations at the request of the attending physician, to verify the diagnosis. 3 Advice, on request, with respect to admission of a patient to a hospital, a sanatorium, convalescent home or similar health station. 4 Supervision of the time a patient remains in hospital and so on. The consultant may examine the patient within the institution in the presence of the attending physician. At such examinations the authority of the attending physician must remain intact, the routine of the institution must not be interrupted except when absolutely necessary. 5 Opinions if requested on the feasibility of special procedures and of the use of therapeutic substances.

In addition, the medical consultant advises the insurance society on all questions pertaining to public health in general, especially by helpful suggestions with respect to the campaigns against tuberculosis, venereal diseases, cancer and deformities as well as with respect to the care of diabetic patients, the welfare of mothers and infants, eugenics and racial and social hygiene. He likewise supervises the care of patients who remain in their own homes. He must keep accurate records of his medical activities, including statistical tables and detailed transcripts of all prescriptions written.

News of the Universities and Student Bodies

Despite the fact that only a short time ago the universities and student bodies were reported on (*THE JOURNAL*, May 8, p 1664, and May 15, p 1728) several interesting new developments have occurred. A maximal quota of students is prescribed for the various universities with a view to a reduction of the number of matriculants. Of late the revision of the present arrangement of semesters has been discussed and it has been pointed out that the time required for academic training would be substantially shortened if a system of three terms per annum were adopted in place of the present two semesters. Such a change, it is urged, would in turn facilitate the earlier marriages of university graduates and assure a larger number of children of such marriages. Meanwhile the required time of attendance at the gymnasiums and so on, namely, the time spent at school before matriculation in a university, has actually been shortened by about a year. But now the national minister of public instruction comes forward with a rejection of the proposal to revise the present two semester schedule. He justifies his stand on the grounds that the members of the university faculties must first of all be allowed ample time in which to carry on their own research activities. Since teaching imposes a heavy burden on the professors and other faculty members, research activities can be carried on profitably and systematically only within a continuous period during which these men are relieved of teaching duties, and this period should be as long as is practically possible. In addition there fall within the so-called vacation period a number of examinations, excursions and scientific field trips which make demands on a professor's time. From the standpoint of the students' welfare

too a sufficient interval between semesters is necessary, since it can be spent in reviewing the material studied during the school year and in the acquisition of practical experience. In fine, the real danger to scholarly preparation and diminution of scholarly activities that inheres in any overburdening of either teachers or pupils must be guarded against.

All German students who contemplate matriculation in a university for the summer semester 1937 must submit beforehand to physical examination by a physician attached to the Nazi party's bureau of public health. A "health album" will be made out for each person examined and this document will consist in the main of data on the genetic background of the prospective matriculant's family.

By the terms of a recent decree issued by the minister of public instruction acting in collaboration with other high officials and with the foreign office, Jews of German nationality are no longer permitted to take the doctoral examinations and are thus automatically excluded from graduation. The honorary renewal of the diploma, long a customary part of a doctor's jubilee celebration, also is now denied to Jews. Jews of mixed blood may, however, take their degrees. For students of medicine and dentistry who are of Jewish extraction special provisions are made, since for them graduation can take place only subsequent to licensing as physicians and dentists. All persons classed as "Jewish hybrids" are afforded the opportunity to acquire the doctor's degree (but, as mentioned before, they may not be licensed as physicians or dentists) on condition that after passing the state examination they obtain permanent positions abroad. In such cases authentic proofs must be forthcoming that the position in question is already secure and permanent or that the prospects for obtaining such a post are certain. The candidate who receives his degree under the foregoing circumstances must be made to realize explicitly that he has no possible chance of securing a license to practice in Germany. The new decree also provides that the minister of public instruction himself shall examine the character of each doctoral candidate with particular regard to the candidate's political activities. Non-German Jewish hybrids are placed on a par with other foreigners and may obtain the doctor's degree in medicine without any condition. But persons who have been legally deprived of German citizenship through revocation of naturalization or otherwise do not enjoy the status of foreigners, not only is it impossible for persons in this category to receive a degree, degrees already held by them are automatically invalidated with the loss of citizenship.

As to actual university instruction, the idea of a free course of study for all students is under discussion. Perhaps a simplification of the complicated system of matriculation and tuition fees will be the next development.

The National Bureau of Student Guidance has been raised to the status of a main bureau of the Nazi party. The supervision of all German university students is thus incorporated within the party and the partisan control of student life consolidated.

In the place of the various student publishing bureaus there is now a single "Students' Press Service," which is the official news agency of the national bureau. The bureau purposes to carry on a reorganization of the universities and of the entire field of learning on the basis of the Nazi weltanschauung. The bureau interests itself in such matters as the reorganization of student academic affairs, the struggle for the "new pattern of existence" and the "new educational ideals of academic youth." In an article contained in the first number of the bureau's new student news publication it is stated that the selection of matriculants in the university will in future be based primarily on political considerations. To the selective process of former times, which was based on individual intellectual promise without regard to the collective national life is now opposed the present day method of selecting matriculants in the univer-

sities, namely, by way of the Hitler Youth, the work service and the army and navy.

The new student paper is also authority for the statement that at Heidelberg 67 per cent of the students belong to one or another of the Nazi organizations. This figure or one slightly lower may be regarded as average for the entire German reich.

Formerly the alumni of a university were accustomed to maintain relations with their student societies by membership in alumni associations of so called old grads. Today there is but one recognized such alumni organization, the Nazi "Students' Campaign Auxiliary." This group constitutes a sort of students' benefit society, each member pays in a monthly contribution which goes to the aid of university students. This collection of funds from the alumni, in addition to being an idealistic gesture of cooperation, contributes materially to the formation of the new academic life. In April of this year, for example, the influx into the auxiliary took place at the rate of from 100 to 200 new members each day.

VIENNA

(From Our Regular Correspondent)

June 9, 1937

Health Exposition in Vienna

A great health exposition called "The Foundation of Life and Health" opened in Vienna in May, to continue till the end of June. The enterprise was planned by cooperating groups including the Vienna department of health, the sick insurance and the pharmaceutical and chemical industries. The most important exhibit is that of the German Museum of Hygiene, Dresden. The Ministry of Public Health presents its exhibits under the title "A Healthy Citizen in a Healthy Country." Detailed diagrams, tables, charts, pictures and objects are used to illustrate the multifarious governmental activities in the fields of care of the health, preservation of health and restoration of health. Particular sections are gotten up to depict how the state seeks to protect the workers at various occupations, while other sections deal with public health service in general, institutions for the sick, and rescue methods. General and special welfare agencies also receive adequate representation. Among other exhibits of unusual interest are those of the Alpine Rescue Service, the Aerial Protection Service and the Food Inspection Commission. The Ministry of Public Instruction provides an array of posters, photographs and graphic charts, all of which serve to illustrate various aspects of the hygienic education of youth. This exhibit covers the successive phases of formal education from the kindergarten, through the elementary and secondary schools up to the university. Most instructive are the Ministry of Social Service Administration's demonstrations of the various methods of establishing the purity of a community's drinking water. This department also has on display an interesting collection of pictures and charts which illustrate the campaigns against various diseases. All these exhibits are enjoying a throng of visitors. The greatest interest, however, is evoked by the "glass man" from the German Museum of Hygiene. This exhibit, officially styled "The Miracle of Life, consists of a manikin so constructed as to permit a comprehensive idea of the wonders of the human organism. From supplementary diagrams and pictures and from the incredibly faithful preparations the visitor learns of the 222 bones which form the human skeleton, that four tibias are able to support the weight of eighty persons, and similar facts. A noteworthy model of the circulatory apparatus demonstrates how the heart keeps the organism supplied with blood and how the circulatory reflux takes place: a pump constructed in the exact form and proportions of the human heart drives a colored fluid representing the blood through tubes of red and blue glass corresponding exactly with the principal blood

vessels By this device the work of the heart, which in three minutes pumps some 25 liters of blood through the body, is demonstrated with the utmost clarity The astonished observer learns that in twenty-four hours a performance requiring many horse power is accomplished A cube of 1 meter filled with the corresponding number of correctly shaped and colored imitation erythrocytes and leukocytes illustrates the number of blood corpuscles in a cubic millimeter The million times over magnifications permit one to observe the actual mechanics of the blood and one learns that if all erythrocytes of one human organism were placed together end on end they would form a chain 200,000 kilometers in length (a distance equal to five times around the earth's equator) The finer structures of the lungs are shown by colossal magnifications of the alveoli and the observer is informed by the accompanying legend that each human being possesses 300,000,000 such pulmonary alveoli In another section the anatomy and relative size of the brain are portrayed Instructional models illustrate the anatomy and physiology of the auditory apparatus, including the labyrinth, and show how disturbances may arise within it The sense of smell is only moderately developed in human beings One learns that the olfactory surface in man is barely 250 square millimeters in area, whereas that of the dog, an animal endowed with an excellent sense of smell, is about ten times greater In other representations of the human organism the onlooker is able by pressing a switch to illuminate the sets of interrelated organs and to study the fine structure and coordination of the various parts There is also a consecutive series of human embryos and fetuses in transparent visualization which portray development from conception to parturition The phenomenon of conception is illustrated by large pictures There are also preparations of the finer histologic structure of the brain as well as a gigantic model of that organ in which more than 1,000 small colored lamps are connected in a maze of wires Each wire represents a particular path of conduction, by pressing the corresponding button the related systems of nerve tracks become illuminated Not only the layman but also the physician may profitably observe the various ramifications of the motor, sympathetic and reflex systems as well as the paths of nervous conduction which control speech, hearing and vision This model alone is a real curiosity, a miraculously accurate histologic and pathologic representation of the brain

In addition to the central section of the exposition there is an exposition of prophylactic hygiene in which is illustrated everything that contributes to the prolongation of human life For the bulk of this material, eugenics is the dominant theme There are exhibits on the care of children and adolescents, dental hygiene, proper nutrition, first aid in emergencies, social insurance and the study of the curative forces of nature ultra-violet "emanations from ice and snow," for example Every province of public health service likewise finds representation here The importance of the modern sewerage system, the fight on disease, the care of premature infants, the comparative values of various foods and the milk and grain economies are brought before the visitor in an easily comprehensible form

Medical "Jubilee Week"

A few days ago the Gesellschaft der Aerzte of Vienna, reputed to be the oldest and most renowned medical organization in the world, celebrated its centenary Among its members have been most of the great physicians of the old Austria, men whose names are among the most illustrious in the history of medical science The role of this society in the development of the entire medical field is too well known to be dwelt on here Many of the most significant pioneering steps of medical research were first made known to the world in the sessions of this venerable body the laryngoscope and total extirpation of the stomach and larynx by Billroth, cocaine as an anesthetic for the eye by Koller, the first utilization of roentgen rays

for therapeutic purposes by Freund, the epochal discovery of the causes of puerperal sepsis by Semmelweis, and so on In the 4,000 sessions of the Gesellschaft der Aerzte 15,000 demonstrations have taken place and 3,000 substantial reports submitted, all of which contributed to scientific research and improved public hygiene On the occasion of the society's centenary, a medical festival week was held during which the various scientific organizations centered in Vienna held extraordinary festival sessions Eminent visitors appeared as guests at these meetings to deliver special jubilee lectures The following list contains the names of the principal speakers and their topics Professor Dr de Langen of Utrecht, the circulation Professor Verebely of Budapest, the biology of tumors, Professor Stoeckel of Berlin, radical surgery of the vagina, Professor von Mueller of Munich, the arthritic diathesis, Professor Clairmont of Zurich, pulmonary actinomycosis, Professor Sauerbruch of Berlin, the development of medical science in the nineteenth and twentieth centuries, Professor Wagner of Berlin, ovarian disorders, Professor Pfaunder of Munich, childhood pathology, Professor Wessely of Munich, myopia, Professor Kahler of Freiburg-in-Breisgau, tonsil problems All these speakers are honorary members of the Gesellschaft der Aerzte Besides these lectures there were other lectures and demonstrations by the active Viennese members Professor Fraenkel discussed pathologic aspects of cancer, Professor Wagner-Jauregg the pathology and therapy of tabes dorsalis, and Professor Lorenz "The World Without Cripples" A surprise marked the session of the Society of Internal Medicine when Professor Leriche of Strasbourg discussed "New Trends in Surgery and Medicine," for his paper contained several novel observations made in research on the sympathicus

The celebration was climaxed by the conferring of honorary doctoral degrees by the Faculty of Jurisprudence and Philosophy of Vienna University on the most prominent three members of the Gesellschaft der Aerzte Professor Dr Wagner-Jauregg, Professor Eiselsberg and Professor Horst Meyer The scientists were extended official greetings from the government by the president of the republic and the mayor of Vienna In addition to the academic functions the 600 visiting physicians were regaled with so comprehensive a program of receptions, balls, excursions and other social diversions that no visitor could possibly have left Vienna without a feeling of having been thoroughly entertained

Marriages

VERNON ATWILL TURNER, Bristol, Tenn, to Miss Elizabeth Josephine Parsons of Crookston, Minn, at Bluefield, W Va April 30

ADELBERT LEROY SPILLER JR, Grayville, Ill, to Miss Anna Scharp of Cleveland in Princeton, Ind, in May

THADDEUS MARIA McNAMARA JR, Bakersfield, Calif, to Dr VIRGINIA PETWAY of Atlanta, Ga, recently

SEYMOUR FISKE to Dr CORNELIA FRANCES ROBERTSON, both of New York, in New Fairfield, Conn, July 3

GEORGE BRONAUH EWING, Smith's Grove, Ky, to Miss Anna Geraldine Keen of New York, May 29

JOHN WALTER MARTIN JR, Cleveland, to Miss Evelyn Barbara Spears of Red Bank, N J, June 29

WILLIAM MARTIN SULLIVAN JR, to Miss Alice Elizabeth Campbell, both of Passaic, N J, May 29

JOHN MCCOLLOUGH SMITH Morrilton, Ark., to Miss Margaret Angehr of Clarksville, June 17

OTTIS DEWEY SEABAUGH to Miss Dorothy Achilles, both of Webster Groves, Mo, June 5

WHITMAN MEAD REYNOLDS to Miss Phebe Root, both of Greenwich, Conn, May 22

COVAN JOHN PEISEN to Miss Almeda Garn, both of Des Moines, Iowa, June 18

Deaths

William Joseph Hogan, Torrington, Conn., Yale University School of Medicine, New Haven, 1898, member of the Connecticut State Medical Society, fellow of the American College of Surgeons, attending surgeon and chief, surgical staff, Charlotte Hungerford Hospital, consulting surgeon to the Litchfield County Hospital, Winsted, formerly member of the board of education, and health officer, aged 61, died, May 22, of arteriosclerosis and hypertension.

Reese Q. Lillard, Lebanon, Tenn., University of Nashville Medical Department, 1890, University of Tennessee Medical Department, Nashville, 1891, formerly secretary and executive officer of the state board of health, member of the Tennessee State Medical Association, at one time United States Commissioner, director of the census and United States marshal for the Middle District of Tennessee, aged 74, died, May 3, in the Vanderbilt Hospital, Nashville.

Edward Warren Sikes, Freeport, Ill., Hahnemann Medical College and Hospital, Chicago, 1902, member of the Illinois State Medical Society, president of the Stephenson County Medical Society, on the staffs of the Evangelical Deaconess Hospital and St. Francis Hospital, served during the World War, aged 61, died, May 5, in the Presbyterian Hospital, Chicago, of acute ascending suppurative hepatitis.

Gustave Lippmann, St. Louis, Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, 1892, formerly assistant professor of pediatrics, St. Louis University School of Medicine, member of the American Academy of Pediatrics, aged 68, on the staffs of St. Louis Children's Hospital and the Jewish Hospital, where he died, May 23, of carcinoma of the stomach.

Willard Mercer Lane, Washington, D. C., University of West Tennessee College of Medicine and Surgery, Memphis, 1914, Howard University College of Medicine, Washington, D. C., 1916, assistant professor of surgery at the Howard University College of Medicine, on the staff of the Freedmen's Hospital, aged 50, died, May 10, in the Johns Hopkins Hospital, Baltimore.

Lucien Carl Feemster, Tupelo, Miss., Memphis (Tenn.) Hospital Medical College, 1897, member of the House of Delegates of the American Medical Association in 1915, member of the Mississippi State Medical Association, past president of the board of health of Nettleton, formerly on the staff of the Tupelo Hospital, aged 64, died, May 25, of cerebral hemorrhage.

Daniel Francis Hayes, Chicago, Northwestern University Medical School, Chicago, 1912, assistant clinical professor of surgery, Loyola University School of Medicine, fellow of the American College of Surgeons, served during the World War, on the staffs of St. Anne's and Cook County hospitals, aged 48, died, May 11, of coronary thrombosis.

Charles A. Donaldson, Tucson, Ariz., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1885, member of the American College of Radiology and the Arizona State Medical Association, formerly a practitioner in Minneapolis, past president of the Hennepin County (Minn.) Medical Society, aged 74, died, May 3.

Henry Harlan Langdon, Cincinnati, University of Cincinnati College of Medicine, 1925, member of the Ohio State Medical Association, acting superintendent of the Cincinnati General Hospital, served during the World War, aged 40, died, May 6, in the Christian R. Holmes Hospital, of teratoma of the testicle with metastases to the lung.

Warren C. Goodwin, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1902, assistant demonstrator of anatomy at his alma mater 1906-1911, member of the Medical Society of the State of Pennsylvania, aged 73, died, May 24, in the Presbyterian Hospital, of hypertrophy of the prostate and pulmonary abscess.

Henry Milnor Joy, Calumet, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, past president of the Houghton County Medical Society, fellow of the American College of Surgeons, served during the World War, formerly member of the state board of medical examiners, aged 67, died, May 15.

William Bailey Murphy, Snow Hill, N. C., University College of Medicine, Richmond, Va., 1903, past president of the Greene County Medical Society, at one time vice president of the Medical Society of the State of North Carolina, aged 59, died, May 4, in the Duke Hospital, Durham, of lymphatic leukemia.

Edward Genung Nugent, Rochester, N. Y., Columbia University College of Physicians and Surgeons, New York, 1897, past president of the Monroe County Medical Society, for many years on the staff of the Rochester General Hospital, aged 66, died, May 9, of arteriosclerosis and coronary occlusion.

Harry Griffith Hirschle, Canton, Ill., Northwestern University Medical School, Chicago, 1912, served during the World War, past president of the Fulton County Medical Society, on the staff of the Graham and Murphy Hospital, aged 49, died, May 14, in Rochester, Minn., of pneumonia.

William McKee Johnstone, Morrisville, Vt., University of Vermont College of Medicine, Burlington, 1906, past president of the Vermont State Medical Society, secretary of the Lamoille County Medical Society, aged 59, on the staff of the Copley Hospital, where he died, May 12, of pneumonia.

William Herbert Prescott, Franklin, Mass., Harvard University Medical School, Boston, 1888, member of the Massachusetts Medical Society and the New England Society of Psychiatry, for many years connected with the City of Boston institutions department, aged 76, died, May 5.

Anna Isabelle McKamy, New Albany, Ind., Northwestern University Woman's Medical School, Chicago, 1897, member of the Indiana State Medical Association, formerly on the staff of St. Edward's Hospital, at one time city health officer, aged 73, died, May 12, in Mattoon, Ill.

Edward Griffith Maupin, Portsmouth, Va., University of Virginia Department of Medicine, Charlottesville, 1877, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878, member of the Medical Society of Virginia, aged 86, died, May 18.

Clyde Robert McConnell, Dayton, Ohio, Ohio Medical University, Columbus, 1904, formerly member of the board of education of Deercreek township, on the staff of St. Elizabeth Hospital, aged 66, died, May 29, in the Miami Valley Hospital, of carcinoma of the pylorus.

John Henry Schaeffer, Philadelphia, Medico-Chirurgical College of Philadelphia, 1903, served in the medical corps as a member of the draft board during the World War, aged 61, died, May 17, in the Episcopal Hospital, of acute streptococcal pharyngitis and laryngitis.

Frank H. Lattin, Gaines, N. Y., University of Buffalo School of Medicine, 1899, formerly health officer of the town of Gaines, and county coroner, for many years a member of the state legislature, aged 75, died, May 23, of cerebral hemorrhage and arteriosclerosis.

John Marion Hooper, Batesville, Ark., Memphis (Tenn.) Hospital Medical College, 1896, member of the Arkansas Medical Society, county health officer, served during the World War, aged 67, died, in May, of injuries received in an automobile accident.

William Ethelbert McConnell, Pittsburgh, Harvard University Medical School, Boston, 1921, fellow of the American College of Surgeons, surgeon to the Western Pennsylvania and Montefiore hospitals, aged 42, died, May 16, of coronary occlusion.

Edward Brent Houston, Murray, Ky., Louisville (Ky.) Medical College, 1907, past president and secretary of the Calloway County Medical Society, part owner of the Keys-Houston Clinic Hospital, aged 56, died, May 9, of cerebral hemorrhage.

Ira D. Kelsheimer, Paxton, Ill., Northwestern University Medical School, Chicago, 1907, served during the World War, secretary and past president of the Ford County Medical Society, aged 57, died, May 29, of coronary thrombosis.

Cyrus Rutherford, Newman, Ill., University of Pennsylvania Department of Medicine, Philadelphia, 1877, for many years a member and president of the school board, formerly mayor and county coroner, aged 86, died, May 2, of pneumonia.

Nathan Walser Mackie, Yadkinville, N. C., Washington University School of Medicine, St. Louis, 1928, also a druggist, aged 37, died, May 21, in the Hugh Chatham Memorial Hospital, Elkton, of chronic nephritis and cirrhosis of the liver.

Carlton Rogers Jewett, Buffalo, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881, for many years visiting physician to the Sisters Hospital, aged 85, died, May 20, of cerebral hemorrhage.

Jacob Dwight Harding, Ogden, Utah, Northwestern University Medical School, Chicago, 1907, member of the Utah State Medical Association, on the staff of the Dee Memorial Hospital, aged 61, died, May 5, of coronary occlusion.

Robert Crump King, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, member of the Illinois State Medical Society, aged 60, died, May 31, of heart disease.

James John McDevitt, Worcester, Mass., University of the City of New York Medical Department, 1886, formerly police surgeon and a member of the board of health of Boston, aged 76, died, May 29, of pneumonia

Enoch George Klimas, Philadelphia, Temple University School of Medicine, Philadelphia, 1915, formerly instructor in medicine at his alma mater, aged 49, died, May 11, of cirrhosis of the liver and chronic nephritis

Robert Watson Hart, Surgeon, U. S. Public Health Service, San Francisco, Medical Department of the University of Cincinnati, 1914, fellow of the American College of Surgeons, aged 47, died, May 18

John H. Gregory, Eldorado, Ill., Rush Medical College, Chicago, 1896, member of the Illinois State Medical Society, served during the World War, aged 63, died, May 23, of carcinoma of the stomach

James Robert Gibson, Inman, S. C., University of Tennessee Medical Department, Nashville, 1892, aged 70, died, May 16, in the Mary Black Memorial Hospital, Spartanburg, of coronary occlusion

John Donald MacPherson, College Point, N. Y., University of the City of New York Medical Department, 1887, on the staff of the Flushing (N. Y.) Hospital, aged 76, died, May 2, of pneumonia

Robert Yantis Littleton, Stout, Ohio, Hospital College of Medicine, Louisville, Ky., 1895, member of the Ohio State Medical Association, member of the local school board, aged 70, died, May 15

Albert N. Legg, Philadelphia, Jefferson Medical College of Philadelphia, 1908, for many years on the staff of the Lankenau Hospital, aged 53, died, May 20, of pulmonary tuberculosis

George C. Essick, Congress, Ohio, College of Physicians and Surgeons, Baltimore, 1893, aged 69, died, May 31, in the Kinney and Knestrick Hospital, Wooster, of chronic interstitial nephritis

Lucian Rufus McCollom, New York, Long Island College Hospital, Brooklyn, 1897, aged 64, died, May 22, in a hospital at Port Washington, N. Y., of chronic myocarditis and arteriosclerosis

David Michael Koontz, New Kensington, Pa., Jefferson Medical College of Philadelphia, 1889, aged 73, died, May 1, in the Westmoreland Hospital, Greensburg, of cerebral hemorrhage

Carl Eugene Neal, Cardington, Ohio, Starling-Ohio Medical College, Columbus, 1914, member of the Ohio State Medical Association, aged 46, died, May 4, of a self-inflicted bullet wound

Edward Joseph Nook, Kalamazoo, Mich., University of Michigan Medical School, Ann Arbor, 1930, city physician, aged 34, died, May 22, in the Borgess Hospital, of pneumonia

John Ezra Myers, Springfield, Ohio, Medical College of Ohio, Cincinnati, 1880, past president of the Clark County Medical Society, aged 83, died, May 3, of cerebral hemorrhage

Edman Payson Fish, Waterville, Maine, Medical School of Maine, Portland, 1900, on the staff of the Sisters Hospital, aged 62, died, May 2, in La Grange, Fla., of aortic aneurysm

Samuel Newton Burchfield, Titusville, Pa., Chicago Homeopathic Medical College, 1887, aged 76, died, May 9, in St. Vincent's Hospital, Erie, of hypertrophy of the prostate

George Thomas Mountford, Coalinga, Calif., Northwestern University Medical School, Chicago, 1909, served during the World War, aged 51, died, May 2, in San Francisco

James LaFayette Houston, Comer, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1898, aged 65, died, May 23, of injuries received in an automobile accident

James Smith McIlhenny, Washington, D. C., Columbian University Medical Department, Washington, 1896, aged 72, died, May 25, in Birmingham, Ala., of coronary occlusion

James W. Jones, Garfield, Ga., University of Georgia Medical Department, Augusta, 1892, member of the Medical Association of Georgia, aged 71, died, May 17, of heart disease

Calvin L. McCoy, Cleveland, Cleveland Homeopathic Medical College, 1901, aged 65, died, May 25, in the Grace Hospital, of hypertension and cerebral hemorrhage

Adeline Eliza Colt Merriam, Hartford, Conn., Bellevue Medical College of Massachusetts, Boston, 1881, aged 95, died, May 28, of chronic myocarditis and arteriosclerosis

Jay W. Newell, Denver, Ind., Kentucky School of Medicine, Louisville, 1880, member of the Indiana State Medical Association, aged 78, died, May 5, of heart disease

Richard W. Bamber, Waterport, N. Y., University of Buffalo School of Medicine, 1883, aged 83, died, May 9, of coronary thrombosis and cerebral hemorrhage

Mattie Isabel Foster Hill, El Paso, Texas, University of Toronto Faculty of Medicine, 1892, aged 66, died, May 11, of cerebral hemorrhage and hypertension

Charles Miesse, Chillicothe, Ohio, Miami Medical College, Cincinnati, 1892, on the staff of the Chillicothe Hospital, aged 66, died, May 22, of pneumonia

George Ramsdell Pancoast, Palmyra, N. J., Jefferson Medical College of Philadelphia, 1884, aged 76, died, May 22, of chronic myocarditis and nephritis

Ernest L. Haffner, Fairport Harbor, Ohio, St. Louis College of Physicians and Surgeons, 1895, served during the World War, aged 65, died, May 5

Albert N. Seidel, Cleveland, Cleveland Medical College, 1895, aged 68, died, May 4, in the Huron Road Hospital of bronchopneumonia following a fall

Wilbur Fisk Culpepper, Senoia, Ga., University of the City of New York Medical Department, 1884, aged 80, died, May 17, of hypostatic pneumonia

Jacob Goldenberg, New York, University and Bellevue Hospital Medical College, New York, 1903, aged 69, died, May 23, of coronary thrombosis

Samuel J. Patterson, East Palestine, Ohio, University of Louisville (Ky.) Medical Department, 1895, aged 74, died, May 26, of cerebral hemorrhage

Ringgold Scott Mitchell, Washington, Ind., Kentucky School of Medicine, Louisville, 1888, aged 85, died, May 27, as the result of fracture of the hip

Frank Elliott Kendall, Saranac Lake, N. Y., University of the City of New York Medical Department, 1880, bank president, died, May 10

Solomon Goldenkranz, New York, University of the City of New York Medical Department, 1888, formerly coroner, aged 69, died, May 17

Walter Atlee Hickman, Marblehead, Mass., University of Pennsylvania Department of Medicine, Philadelphia, 1895, aged 63, died, May 13

George Jesse Lund, Los Angeles, Rush Medical College, Chicago, 1882, fellow of the American College of Surgeons, aged 77, died, May 10

John I. Groves, Champaign, Ill., Hahnemann Medical College and Hospital, Chicago, 1880, aged 83, died, May 1, of mitral insufficiency

Henry Benton Johnson, Pomona, Kan., Rush Medical College, Chicago, 1902, also a druggist, aged 66, died, May 1, of angina pectoris

William Alexander Hatfield, Kokomo, Ind., Curtis Physio-Medical Institute, Marion, 1895, aged 69, died, May 7, of pneumonia

Robert Sidney Lucke, Omaha, Rush Medical College, Chicago, 1884, aged 74, died, May 1, in Santa Ana, Calif., of heart disease

William A. E. Cummings, Glens Falls, N. Y., Albany (N. Y.) Medical College, 1884, aged 77, died, May 5, of lobar pneumonia

Julia E. Blatch, St. Louis, American Medical College, St. Louis, 1891, aged 66, died, April 11, of chronic interstitial nephritis

Elmor C. Jefferies, Rea, Mo., St. Joseph Medical College, St. Joseph, Mo., 1888, aged 78, died, May 9, of chronic myocarditis

James Monroe Capps, Bakerville, Tenn., Vanderbilt University School of Medicine, Nashville, 1895, aged 72, died, May 4

David Patton Burleson Jr., Spruce Pine, N. C., Medical College of Virginia, Richmond, 1935, aged 27, died, May 16

Daniel Phelan, Kingston, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1877, aged 83, died, May 2

Gail Barr Dunkle, Los Angeles, Jefferson Medical College of Philadelphia, 1897, aged 63, died suddenly, May 5

Riley Park McElroy, Ada, Ohio, Baltimore Medical College, 1903, aged 66, died, May 13, of pneumonia

Lewis Minot Daniels, Columbia, S. C., Leonard Medical School, Raleigh, N. C., 1913, aged 46, died, May 2

Carl Hagen, Silver City, N. M., Hospital College of Medicine, Louisville, Ky., 1891, aged 78, died in May

Sidney D. Lawson, Kansas City, Mo., Ensworth Medical College, St. Joseph, 1908, aged 55, died in May

Bureau of Investigation

PISO'S IN NEW RAIMENT

Piso's Labels Show Interesting Evolution in Nostrum Industry

"Piso's for Coughs," formerly "Piso's Cure for Consumption," "Piso's Cure" and "Piso's Remedy, a Medicine for Coughs and Colds," "prepares for winter" in a new, cream-colored package, according to the June 5, 1937, issue of *Drug Trade News* a newspaper devoted to the drug industry. *Drug Trade News* which reproduced the repackaged Piso's cough preparation, might (but, of course, it did not) also have reproduced the evolution of the Piso label, as shown by the accompanying illustrations.

The Piso remedy has long been known to the files of the Bureau of Investigation. Before the passage of the Food and Drug Act (1906), which specifically prohibits false statements in or on the trade packages of 'patent medicines,' Piso's was advertised as a "cure for consumption." After the act became operative, Piso's "cure" became "a medicine for coughs and colds."

Samuel Hopkins Adams, in his "The Great American Fraud" series, which ran in *Collier's* some years ago, said:

Piso's Consumption Cure extensively advertised a year or two ago is apparently withdrawing from the field so far as consumption goes and the Piso people are now more modestly promising to cure coughs and colds. Old analyses give as the contents of Piso's Cure for Consumption alcohol chloroform opium and cannabis indica (hasheesh). It is therefore another of the remedies which cannot possibly cure consumption but on the contrary tend by their poisonous and debilitating drugs to undermine the victim's stamina.

The United States Department of Agriculture on Feb. 8, 1913, published a report on an action filed against the Piso

The center picture is of a recent carton and bottle of Piso's the others are much older one calling the thing a cure and a later one a remedy

Company in the District Court of the United States for the Western District of Pennsylvania by the United States attorney for that district. According to the federal report, analysis of the Piso nostrum showed the following results: "total solids, 65.32 per cent, sugar, 64.89, ash, 0.007, petroleum extract from acid solution, 0.084, chloroform extract from alkaline solution 0.028, chloroform, 0.1866 chloroform in 1 ounce, 7/100 minimum. The flavoring agents are methyl salicylate and chloroform with indications of oils peppermint and bitter almonds."

Some years back, when Piso's Cure contained "1/2 grain extract cannabis indica 5 minims chloroform and other valuable ingredients," Piso's was a "trustworthy remedy" in all diseases of the throat and lungs with symptoms simulating those of consumption. Recommendations to "consumptives" by the exploiters of the "trustworthy remedy" included: "We earnestly recommend outdoor exercise, regardless of weather. If you are unable to take such exercise on horseback or on foot exercise in a carriage."

Also noteworthy was the statement "Medicines which cause expectoration must be avoided," when contrasted with a May 29, 1936, report of the Federal Trade Commission, which stated "The Piso Co., Warren, Pa., agrees to stop asserting that 'Piso's for Coughs' is a competent treatment or effective remedy for coughs, unless the allegation is limited to the preparation's value as an expectorant cough mixture."

A Food and Drug Bulletin published by the North Dakota Regulatory Department for August 1933 describes Piso's for Coughs as a green syrup in a brown bottle chloroform present alcohol, none. Just what the "trustworthy remedy" contains today, only the Piso Company knows. And only the Piso Company would know how "working internally," Piso's destroys the cold germs and breaks up infection.

However the Piso Company, Warren, Pa., has "repackaged its cough preparation, using a cream color. The bottle is by the Brockway Glass Company."

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding; and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Pinerva Pine Needle Bath Salts—Pinerva Laboratories, Inc., Milwaukee. Composition: Essentially baking soda (49 per cent) common salt (48 per cent) traces of pine needle oil and a red dye with a small amount of water. For rheumatism, gout, etc. Misbranded because of fraudulent therapeutic claims and because represented to be composed essentially of substances derived from pine needles.—[N J 24096 November 1935]

Novak's Female Drops—John Novak Co., Chicago. Composition: Essentially extracts of plant drugs including cramp bark, glycerin alcohol (38 per cent) and water flavored with clove oil. For female disorders. Fraudulent therapeutic claims.—[N J 24067 November 1935]

Novak's Oil—John Novak Co., Chicago. Composition: Essentially alcohol (52 per cent) chloroform and winter green (each 57 per cent) menthol, oleoresin of red pepper, ammonia and water. For rheumatism, lameness, toothache, etc. Fraudulent therapeutic claims.—[N J 24067 November 1935]

Komet—John Novak Co., Chicago. Composition: Essentially volatile oils including camphor, menthol and winter green with turpentine oil (19.4 per cent) in a mixture of petrolatum and wax. For rheumatism, sciatica, lumbago, stiff neck, etc. Fraudulent therapeutic claims.—[N J 24067 November 1935]

Pyrol—Kip Corp., Ltd., Los Angeles. Composition: Essentially petroleum and zinc oxide with small amounts of cartholic and salicylic acids and essential oils including wintergreen. For boils, piles, ulcers, eczema, etc. Fraudulent therapeutic claims.—[N J 24072 November 1935]

Mastin's Vitamin Tablets—Vitamin Corp., Mastin & Co., New York. James F. Stras, LaCrosse, Wis. Composition: Essentially yeast, calcium glycerophosphate (17 grains per tablet), calcium carbonate (17 grains per tablet), a small amount of an iron compound, nuxvomica extract (0.2 grain per tablet) and a laxative plant extract. For run-down conditions, etc. Fraudulent therapeutic claims.—[N J 24118 November 1935]

Anti Pyrexol—Kip Corp., Los Angeles. Composition: Essentially zinc oxide, small amounts of cartholic acid and essential oils including wintergreen in an ointment base. Antiseptic. Fraudulent therapeutic claims.—[N J 24076 November 1935]

Saratoga Ointment—G. F. Harvey Co., Saratoga Springs, N. Y. Composition: Essentially zinc oxide, boric acid and a small amount of eucalyptol in a petrolatum base. Antiseptic. Fraudulent therapeutic claims.—[N J 24070 November 1935]

Seavigor—Seavigor Co., New York. Composition: Essentially seaweed. For run-down conditions, etc. Fraudulent therapeutic claims.—[N J 24085 November 1935]

Red Raven Spills—Red Raven Corp., Red Raven, Pa. Composition: An artificially carbonated solution of sodium phosphate. For chronic constipation, biliousness, etc. Fraudulent therapeutic claims.—[N J 24071 November 1935]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DIFFERENTIAL DIAGNOSIS OF MIGRAINE

To the Editor—A white man aged 50 complains of recurrent attacks of severe retching, vomiting and headache. He had fever on the ship on which he came to this country in childhood, he worked for many years over a coke oven in a candy factory, nothing else in the history is relevant. The attacks started ten years ago at which time they came every year or two and lasted seven or eight hours. For the past two years the attacks have occurred about every two or three months each attack lasting about twenty-four hours. A period of marked and increased helching precedes each attack for about ten days. The attack starts with frontal headache for five hours (accompanied by spots before the eyes) after which the retching and vomiting begin even though nothing is ingested. The vomitus consists of bile stained fluid of small amount, vomiting is not projectile, there is no abdominal pain or soreness (except after the prolonged vomiting), the stools and urine are of normal color, there is no jaundice, the temperature is normal, examination of the eye grounds, neurologic examination and physical examination give negative results. During the attack the blood pressure is 200/120, 190/100. In the interval between attacks it is 155/110, 140/100, 160/100, 140/90. There is no diarrhea. Deafness of the right ear was discovered accidentally about eight years ago, it is middle ear deafness. The blood Wassermann reaction has been negative twice. Sometimes the patient has headaches and no vomiting attacks. There is rarely much or any nausea. The attacks are apparently becoming more frequent, and since they incapacitate the patient for a few days each time it would be desirable to prevent their recurrence.

MD New York

ANSWER—Under the circumstances one must rule out by a process of elimination such conditions as the gastric crises of tabes, cholecystic disease, intracranial neoplasm or aneurysm, paroxysmal hypertension, duodenal ileus and migraine. Less likely as possibilities are lead encephalopathy, hyperthyroidism, allergy, and carbon monoxide poisoning. The long duration of the complaint, without development meanwhile of objective signs of any real significance, would seem to exclude everything except disease of the gallbladder, duodenal ileus and migraine. As a matter of fact, the evidence favors migraine in a patient with a tendency to hypertension, even though the symptoms had their onset at a period in life later than usual and the pain is not unilateral. Granted that an adrenal paraganglioma can be excluded with reasonable certainty, the increased blood pressure at the time of the seizure might be the result of the pain and retching in a hyperreactive individual. The symptoms are not consistent with any form of heat injury, granting that he still works over a coke oven.

One should search for further clinical and roentgenologic evidence of duodenal ileus and cholecystic disease. A history of sick headaches in a parent, grandparent or sibling would strengthen the possibility of migraine, especially with the satisfactory exclusion of disease in the gallbladder and duodenum. Relief afforded by the hypodermic injection of ergotamine tartrate (1 mg.) at the onset of a seizure would be of further diagnostic value. Granted that the condition is not due to any demonstrable disease or toxemia suggested, treatment with the alkaloid or along other approved lines, with the probable inclusion of vasodilators, should be carried out.

SEBORRHEA OF SCALP IN WOMEN

To the Editor—A blonde school teacher has a severe dry, scaly seborrhea of the scalp. The dryness and severity of the condition are aggravated I believe by too frequent visits to the beauty shop. Recently an area of alopecia about the size of a half dollar (30 mm.) has developed over the parietal area. Bearing in mind that she is very blonde and takes great pride in her appearance, will you kindly send me information concerning treatment that will be most efficacious. She has a permanent wave. Kindly omit name.

MD Iowa

ANSWER—Present-day modes of hair dressing are undoubtedly unhygienic. Pasting the hair down favors infection. Brushing, the most valuable form of massage, is prevented by the fear of disturbing waves. Argument is futile and the physician must work under this handicap.

An examination of the scales, both by direct soaking with potassium hydroxide and by culture on Sabouraud's medium should be made before instituting treatment. If no unusual organism is found, try to persuade the patient to shampoo the hair Friday evening, followed by the application of a stimulat-

ing ointment such as salicylic acid 1 Gm., precipitated sulfur 3 Gm. and juniper tar 3 Gm. in sufficient rose water ointment to make 30 Gm. The ointment is to be rubbed in thoroughly in small amounts between the parted hair. On Sunday evening this can be washed out, and a lotion of chloral hydrate 6 Gm. resorcinol monoacetate 6 Gm., spirit of formic acid 20 cc. and sufficient spirit of myrcia to make 120 cc. may be applied once daily during the week. The ointment application is to be repeated the following week end. If this program is rejected, the lotion alone may be of some benefit. Instead of brushing, a thorough massage should be given the scalp once a day.

The patch of alopecia may be due to brittleness of the hair, in which case it will disappear as the scalp recovers its general health, or it may be a beginning alopecia areata. If it does not disappear with a few months of treatment, it should be given a dose of ultraviolet rays sufficient to cause a decided erythema followed by peeling. After peeling takes place the treatment should be repeated with an appropriate increase in its strength.

If ultraviolet rays are not available, the bald spot may be painted with a mixture of one part of phenol to four of lactic acid. As soon as the skin recovers from one application, this is to be repeated.

The patient's general condition should be investigated and any abnormality treated.

BLOOD VOLUME INDEX

To the Editor—Will you let me know the best method for determining the red cell volume index, especially in children. I mean the average size of the red cells in a patient as compared with their normal size. The methods of Haden and others are accurate but require a large quantity of blood and are therefore unsuitable for children. Sanford and Magath's volume index tube, though requiring a less amount of blood, is also unsuitable. If the Van Allen hematocrit tube is used Stitt (rd 8) advises that the blood mixed with a small quantity of anticoagulant be drawn up until the bulb is about one-third full. I fail to understand why such vague amounts should be used in carrying out a delicate test. With the Daland hematocrit in which no anticoagulant is used it is not understood why the height of the red cells is to be multiplied by 2 for obtaining the volume percentage, moreover the blood is apt to coagulate in these tubes. If the projection method is used the cells at the periphery of the field are distorted and therefore give a wrong reading. Recently it has been given out that a Baltimore firm has developed a new method for obtaining more accurate results. In these circumstances I would greatly appreciate a detailed description of the test that would be most satisfactory. Kindly omit name and address.

IRFLEY, India

ANSWER—These objections to the projection method and to the Daland hematocrit are quite understandable. The height of the column of red cells in the latter was probably multiplied by 2 in order to obtain a figure roughly in proportion to normal.

With the Van Allen hematocrit, blood is drawn exactly to the top of the calibrated column and then a small amount of anticoagulant is added. The latter must be isotonic with the blood, but its amount need not be measured, for, during centrifugation, the red cells from an accurately measured amount of blood are thrown to the bottom of the calibrated portion of the tube and the height of this column is read. The chief source of error with the Van Allen tube is the difficulty of preventing leakage. The sealing device supplied is not always adequate even when fresh rubber pads are used. A more accurate method, which requires a minimal quantity of blood, has been described by Guest and Siler (*J Lab & Clin Med* 19:757 [April] 1934), but this involves the use of a special centrifuge head and measuring microscope, the instrument described by Mason (*J Lab & Clin Med* 20:318 [Dec] 1934) is somewhat more practical.

Perhaps the Baltimore method to which reference is made is the Wintrobe hematocrit (*Am J M Sc* 185:58 [Jan] 1933). This is a tube of uniform bore, sealed at one end, on which is etched a millimeter scale 10 cm. in height. Blood is first mixed with an anticoagulant (12 mg. of dry ammonium oxalate and 0.8 mg. of dry potassium oxalate, per cubic centimeter of blood) and then the tube is filled with the aid of a capillary pipet. Centrifugation is carried out at 3,000 revolutions per minute for thirty minutes. One cc. of blood is needed for this instrument. This amount can be obtained from the finger but is more easily secured by venipuncture. After the red cells have been packed completely the height of the column of red cells is read.

Whatever method for centrifugation may be used the mean size of the red cells is determined by dividing the volume of packed red cells by the red cell count. The volume of packed red cells as measured in cubic centimeters per thousand cubic centimeters of blood, divided by the red cell count in millions, gives the 'mean corpuscular volume' in cubic microns. Normally the mean corpuscular volume averages 87 cubic microns.

Values above 92 cubic microns indicate macrocytosis, those below 82 cubic microns microcytosis (Wintrobe M M Anemia—Classification and Treatment on the Basis of Differences in the Average Volume and Hemoglobin Content of the Red Corpuscles, *Arch Int Med* 54 256 [Aug] 1934). It is better to express red cell size in this absolute measure but one may still calculate the "volume index," which gives the mean red cell size in proportion to an arbitrarily fixed "normal." For volume index, 424 cc per hundred cubic centimeters of blood is taken as the equivalent of 100 per cent packed red cells that is, the volume of packed red cells as determined is divided by 424 and multiplied by 100. This gives the volume of packed red cells in proportion to "normal." This value divided by the red cells in percentage of "normal" (red cell count divided by 5 and multiplied by 100), gives the volume index.

SPIDER BITES

To the Editor—A number of spider bites have occurred during the last twelve months most of which are of the black widow species. My textbook contains only short sketches of the spiders the symptoms of their bites and the treatment. How can the species be determined—the one producing immediate severe constitutional symptoms and the one or more producing necrosis? What will relieve the pain of the black widow bite? Why should the bite of the black widow produce no constitutional symptom of any consequence in one patient when the bite was on the buttocks and bare skin? I administered calcium gluconate 10 per cent in the muscle and vein about one hour after the bite and no other drug was given. Where can I obtain a textbook on the American spider? I have found morphine almost useless in doses ranging up to 3 grains (0.2 Gm.) during a twenty four hour period in the relief of pain. I have tried magnesium sulfate in the vein also with unsatisfactory results even when combined with morphine in heavy doses. Hot baths and local applications of heat also have been used. Must the patient suffer violently for a period of twenty four to thirty six hours or is there something more that can be done? One of my friends gave his patient antivenin or antiserum and this is now available. His patient did not get what he considered satisfactory results. Any suggestions as to treatment or other information will be appreciated.

THOMAS F HUDSON M D Luvora Ark

ANSWER—Of all of the hundreds of species of spiders found in this country, it appears that *Latrodectus mactans*, or black widow spider, is the only one apt to produce severe systemic symptoms. A general description of the various kinds of spiders is contained in *The Spider Book* by John Henry Comstock, published in the Nature Library in 1920 by Doubleday, Page & Co, but a more recent monograph on spider poison is presented in *Le venin des araignees*, by J Vellard, published by Masson & Cie in 1936. The literature on spider bite poisoning, with special reference to North America, may be found in three articles by Emil Bogen (*Arch Int Med* 38 623 [Nov] 1926, *Ann Int Med* 6 375 [Sept] 1932, *California & West Med* 45 31 [July] 1936).

Latrodectus mactans is a shiny, coal black spider, usually brilliantly marked with red or yellow or both. The female, which is always the one responsible for the bites reported, is often half an inch in length and may stretch its slim, glossy black legs over as much as 2 inches. The markings vary somewhat, the most constant being a bright red patch, shaped like an hour-glass, on the ventral surface of the abdomen. Its unesthetic coarse, straggly, three dimensional web aids in its recognition.

Local lesions have been reported in some instances of black widow spider bite but are exceptional and may often be ascribed to associated infection, local treatments or special allergy or idiosyncrasy of the subject. On the other hand, the ejection of the poison is under control of the spider and does not occur with every bite, so that numerous instances are recorded in which the bite was not followed by any symptoms, local or general. Local necrotizing lesions have been reported most often from *Glyptocramum gasteracanthoides* of Peru a gray orbweaver, and *Aranea audax* of Argentina, but in this country only a few instances have been reported from bites of the tarantula the trap door spider or other large hairy forms and spider bite as a cause of local lesions, although frequently suspected, has rarely been proved.

The intravenous injection of 10 cc of 10 per cent calcium gluconate or other calcium salts, repeated as required, generally relieves the acute pain even more effectively than the intravenous injection of magnesium sulfate, which also has been recommended, but this may be supplemented by hot baths or hot applications, spinal puncture, and the administration of convalescent or immune animal serum. The inadequacy of opiates in controlling the acute symptoms of arachnidism has been repeatedly remarked, but sedatives may be useful in conjunction with the foregoing more specific treatments and in the care of the residual paresthesias that sometimes persist. Local treatment should be confined to a simple antiseptic application, as

the scarification and cauterization or suction useful in other kinds of venomous bites seem to have no effect on the systemic development of arachnidism and only increase the danger of local infection.

POPLITEAL ARTERY PULSE—MOUTH AND RECTAL TEMPERATURES

To the Editor—What is the proper method of obtaining the popliteal artery pulse? In what percentage of cases is it palpable? Is it the mouth temperature (of 98.6 F) or the rectal temperature (of 99.6) that is considered the normal temperature of the body? Why are rectal thermometers marked to indicate normal at 98.6 when the real normal for that region is 99.6?

M D New York

ANSWER—The proper method of obtaining the popliteal artery pulse is to flex the knee, thus relaxing the popliteal fascia that overlies the artery. With the knee flexed, the palpating finger may be deeply pressed into the popliteal space at a point that marks the junction of the middle and upper thirds of the space. As a general rule the pulsations of the artery may be felt at this point unless they are obscured by an excessive amount of fat or, occasionally, by fluid in the popliteal bursa. It should be remembered that the artery is rather deeply situated is covered by the vein and nerve and is protected by a heavy fascia and fat and connective tissue, hence its pulsations are not as easily felt as those of much smaller arteries that are more superficially placed.

Strictly speaking it is impossible to give any single figure that represents the "normal temperature of the body." This is true because the temperature of different parts of the body taken at the same time will show a variation and the temperature of the same portion of the body taken at different times during the day will show variation. When one speaks clinically of the normal temperature of the body, one actually means the normal temperature of the body in the places where it can be conveniently measured.

The measurement of the temperature in degrees Fahrenheit, several times during the day in a large number of normal persons resulted in readings of 98.96 for the rectum, 98.45 for the axilla and 98.36 for the mouth. It should be remembered that these are averages and that the actual readings in the same person will sometimes vary as much as from 1.5 to 2 degrees in twenty-four hours. The mean of these averages is 98.59 and from this comes the figure 98.6 on the clinical thermometer. This figure represents the mean normal temperature of the body in those places in which it can be conveniently measured.

SYPHILIS IN PREGNANCY

To the Editor—In October 1935 a married woman aged 18 had an abortion at two months after taking a bus trip to West Virginia and back. The long trip seemed sufficient reason for the abortion. She made a good recovery from the abortion. In September 1936 she was referred back to me for a hazy left cornea (interstitial keratitis) and a Kahn test. This was 4 plus and she has been getting nearsphenamine from September to December together with bismuth salicylate in oil. She reported pregnancy in October 1936 and her abdomen is now somewhat enlarged. In January 1937 I started mercurosal intravenously and will give it for a month or six weeks. Then I expect to return to nearsphenamine and the bismuth compound. If her baby is apparently normal and at full term should she nurse it? I can find no other member of the family with a Kahn positive reaction. Perhaps it is an inherited condition in the patient. Please discuss the case. Please omit name. M D Michigan

ANSWER—It seems probable that this young woman has an acquired rather than a congenital syphilis and considering her age and recent marriage it is doubtless not an old infection. The absence of syphilis in the family is against congenital infection.

The abortion may or may not have been due to her syphilitic infection and while most terminations of pregnancy due to syphilis occur later in pregnancy this is not an infallible rule.

She should be treated actively throughout pregnancy, as a recent infection is dangerous to the fetus. The percentage of fetal syphilis is much higher in women who have syphilis with a positive Wassermann reaction than in those in whom this test is negative. The treatment indicated should be adequate. Some believe that nearsphenamine may be continued throughout pregnancy but others feel that there is danger of a serious reaction late in gestation and prefer the use of heavy metals in the later weeks.

When the infant is born a cord Wassermann test should be done and if possible a roentgenogram of the long bones be made to diagnose any presence of a syphilitic infection. The positive cord Wassermann is a reliable test but the negative reaction is not conclusive and blood should be secured later for a repetition of the test. The examination of the placenta often does not give positive evidence either for or against the presence

of fetal syphilis. The safest course to pursue is to give the new-born infant a course of antisyphilitic treatment.

There is no reason why the mother should not nurse her baby so far as the transmission of this infection is concerned. Naturally the treatment of the mother should be carried to its conclusion after the baby is born.

The main objective of the treatment of the prospective mother is not so much to effect a cure in her as to prevent transmission of the disease to the fetus. A woman treated prior to pregnancy is less apt to give birth to a syphilitic infant than one in whom the treatment is begun after conception has taken place. The earlier in pregnancy the antisyphilitic treatment is started the higher the percentage of favorable results for the fetus will be.

Once a woman is syphilitic, she should receive treatment in each successive pregnancy as there is always some possibility, though a diminishing one, that the fetus may be affected if antepartum treatment is not administered.

ERYTHROBLASTIC ANEMIA

To the Editor—A boy aged 13 is the only normal offspring the two living children a girl of 7 and one of 3 months appear to have erythroblastic anemia (Cooley) and we are assured that the deceased boy and girl (aged 19 months and 3 years respectively) were victims of the same disease. The parents are healthy Italians. They know of no relatives afflicted with the disease, their Wassermann reactions are negative. We are unable to discover any dietary deficiency or any intoxicating agent. The older child has received extensive x-ray therapy to the spleen, liver and long bones. She presents a muddy yellow color and a definite mongoloid facies. The recent appearance of these familiar characteristics in the youngest child prompted the mother to seek medical advice. In addition the spleen is enlarged in the older child it occupies about a third of the abdomen and is very hard and slightly nodular in the infant it may be felt only during the inspiration and is moderately hard and smooth. There is no enlargement of the liver and only slight enlargement of the cervical lymph nodes in the older child. There are no other physical manifestations and the mother insists that there have been no other symptoms. The laboratory data are as follows:

Older child

Red blood cells	1,950,000	Small lymphocytes	40 per cent
Hemoglobin	50%	Large lymphocytes	40 per cent
Color index	1.3	Neutrophils	44 per cent
Platelets	93,600	Eosinophils	0 per cent
Bleeding time	3 minutes	Basophils	0 per cent
Coagulation time	3 minutes	Neutrophilic myelocytes	16 per cent

The infant

Red blood cells	2,785,000	Small lymphocytes	66 per cent
Hemoglobin	55%	Large lymphocytes	0 per cent
Color index	1	Neutrophils	24 per cent
Platelets	860,000	Eosinophils	0 per cent
Bleeding time	3 1/2 minutes	Neutrophilic myelocytes	8 per cent
Coagulation time	4 minutes	Basophils	0 per cent
		Basophilic myelocytes	2 per cent

Blood smears of both children reveal numerous nucleated red blood cells (normoblasts and megaloblasts), polychromatophilia, stippling, anisocytosis and poikilocytosis. The fragility test and icterus index were not done. The urine and feces are normal in both cases. Roentgenograms of the skull of the infant reveal no abnormality but the conditions found in the older child are fairly characteristic: the bony cortex is thin and the medulla is considerably thickened with prominent trabeculations. No definite abnormality was observed in the long bones. We are looking forward to your opinion of the diagnosis and would greatly appreciate your suggestion as to the treatment of these cases.

D. T. MARTIN, M.D.
E. A. SCHENKAYNER, M.D.
Donaldsonville, La.

ANSWER—This family of children belonging to the race that originated along the north shore of the Mediterranean presents a severe and progressive type of anemia. That the disease is familial and that all the children had markedly enlarged spleens and a mongoloid facies suggest erythroblastic anemia or Cooley's disease. No mention is made of thickened and somewhat porous bones at the vault of the skull, though the other symptoms mentioned suggest the disease. Cooley concedes that polymorphism of the red cells is characteristic and that the presence of nucleated erythrocytes is one of the most striking features of the blood examination. He also believes that hemoglobin is destroyed by fragmentation and that it is irregularly deposited in the cells.

Cooley's disease must be differentiated from sickle-cell anemia or secondary anemias following malaria or hereditary syphilis. The familial nature of the disease with anemia, splenomegaly and leukocytosis and peculiar though characteristic changes in the blood should confirm the diagnosis of erythroblastic anemia which has already been made.

As far as treatment is concerned the various remedies advised in anemia, such as iron, bone marrow and liver have

been administered by mouth, intramuscularly and intravenously. Transfusion and splenectomy have been tried. All methods of treatment up to now have given only symptomatic or temporary relief.

ALLERGY IN INFANT

To the Editor—I have under my care an infant aged 20 months who presents the following problem. Shortly after birth he became covered with eczema and had numerous gastro-enteric upsets. The family history disclosed a maternal grandparent who suffered from bronchial asthma. The child is definitely allergic to milk, eggs, carrots and certain fish. He becomes markedly eczematous and has gastro-enteric disturbances within a day after eating any of the allergens. He has been fed on soy bean formulas (Sobee) and a generally restricted diet until the present time. Thus far he has progressed normally as regards height, weight, dentition, walking and mental development. His skin remains clear and there are no abdominal symptoms while he abstains from the foods mentioned. My difficulty lies in the administration of vitamin D. The child becomes ill with any of the fish liver oils. Viosterol without natural oil produces the same result. Recently crystalline vitamin D was given him (Drysol Winthrop) with the same result. During the summer no particular difficulty was experienced as regards prevention of rickets as the baby was kept outdoors whenever the sun was shining. During the winter I noted for the first time restlessness, rosy head sweating and a tendency toward bowed legs. Ultraviolet irradiation has been used sporadically but the family cannot afford exposures as often as necessary and have too much pride to accept this treatment at my expense. Have you any suggestions? Would violet irradiation alone suffice to cure this impending disease?

M. D. New York

ANSWER—It often happens that children may be allergic when young infants and then change as they grow older. One of the things that is difficult to overcome is prejudice that develops because parents knowing that a child reacted to certain substances, do not want to try these later, at which time the baby may tolerate them.

In this particular case, concentrated vitamin D in small doses, gradually increased should be tried again.

Ultraviolet irradiation alone will suffice to prevent and cure this condition. Drs. Alfred Hess, Steenbock and others have shown that a single erythema dose of ultraviolet rays once a week ordinarily prevents rickets.

To cure rickets, irradiation two three or more times a week is necessary. Irradiated cereals, bread and other foods should be added to the diet. A disturbance of the calcium-phosphorus ratio increases the need for vitamin D so that it may be necessary to add extra calcium or phosphorus to the diet. In this particular instance it might be advisable to determine the serum calcium and inorganic phosphorus so that, if a low calcium is found, calcium gluconate or lactate may be given 1 Gm. two or three times a day. If phosphorus is found to be low, acid sodium phosphate, 1 Gm. two or three times a day, should be given. It is assumed that the child has adequate vitamin C intake.

COBRA VENOM IN PARALYSIS AGITANS

To the Editor—I have read recently in the press of Dr. Macht's cobra treatment of paralysis agitans and would appreciate some information regarding it.

NATHANIEL H. KOPLIN, M.D., Trenton, N. J.

ANSWER—Cobra venom has been employed by French and other European investigators and by Macht and his collaborators in the United States for the relief of the severe pains of advanced malignant disease, neuralgias and chronic arthritis (Macht D. I. Therapeutic Uses of Snake Venom *Am. Rec.* 144:537 [Dec 16] 1936). Macht's pharmacologic studies on animals demonstrated that the drug produces analgesia through its action on the pain areas of the brain. He has also found that cobra venom antagonizes the convulsant action of certain drugs in animals (Macht Experimental and Clinical Study of Cobra Venom as an Analgesic, *Proc. Nat. Acad. Sci.* 22:61, 1936). Further studies along these lines supported the experimental work of Cicardo (Modifications de l'excitabilité nerveuse par action du venin de cobra, *Compt. rend. Soc. de biol.* 120:732-733 1935) and suggested a trial of the drug for the relief of the severe pains due to contractures in advanced Parkinson's disease. In presenting this experimental work before the recent meeting of the American Physiological Society, Macht stated that six cases of Parkinson's disease, which he studied, responded favorably to the treatment. Relief was obtained in three patients complaining of severe pain and in all six cases there was an amelioration of spasticity and tremor. This investigation is still in its experimental stage. It must be understood however that cobra venom is in no sense a cure for paralysis agitans but should be regarded only as a new and nonnarcotic agent which may prove to be helpful in combating some of the distressing symptoms of the disease in its advanced stages, particularly the spastic rigidity and pain.

POSSIBLE MALINGERING OR FEVER OF
UNKNOWN ORIGIN

To the Editor—An unusually well and healthy girl aged 15 years active well built and well muscled a dark brunette and a vixen who knows far more about the ways of the world than her parents has a fever of 102 to 103 F about every two or three weeks which lasts from six to eight hours. Misbehavior is not remotely suspected. In these attacks she seems ill goes to bed and stays out of school for two or three days saying that she is not sufficiently recovered to go to school. After the fever is gone she appears to me to be well enough to go to school. In a recent attack she stayed away from school for ten days. During her absence from school she helped her mother with the washing, drove around with her father in his truck and cleaned the snow off the sidewalk, certainly not signs of being ill enough to miss school. The patient began to menstruate about eighteen months ago but has missed four periods at different times and reestablished them spontaneously. Pelvic examination gives the appearance of a diseaseless virgin. I removed the patient's tonsils two months ago because I felt that the operation was locally indicated. Symptomless large diseased chronic hypertrophic tonsillitis following a history of several attacks. Operation was done in my office with procaine hydrochloride and healing was rapid and uneventful. There was no other disease of the eyes ears nose or throat. The chest is well formed. There is no sign of disease but just to check up a chest roentgenogram was taken which was normal. In the recent attack the Vidal reaction was negative the Kahn reaction was negative and the blood was negative for tularemia. The patient not in my hands had an appendectomy in one of these attacks a year ago. The abdominal pain was negligible at the time. The last two attacks have been accompanied by headache and pain in the back of the neck. Salicylates were given and recovery was complete to my notion in less than twelve hours although not to the patient's notion. After the last attack the red blood corpuscles numbered 5 400 000 the white blood corpuscles 8 500 the differential count was normal and the hemoglobin value 15 Gm. The urine repeatedly has been normal. There are no abdominal symptoms or signs. There is no adenitis. Neurologic examination gives normal results. The skin is clear throughout not even an acne being present. One reason besides the failure to find a physical basis for her attacks for my belief that she has some way to produce them is that they come when her mother has scolded her when there is a written examination at school or at some such time. The patient states that she does not take any drugs or do anything to produce the fever. The mother cannot find any drugs around the house. I watch the thermometer when it is in her mouth but there is no need for this. The fever is there all right—her whole body is hot her face is red and the pulse is around 120—but there is no sweating. I can only think of one legitimate explanation—the patient is very nervous in the attacks—possibly she involuntarily produces a fever through a nervous shock or whatever one might call such a phenomenon. The girl is very clever. I think she is fooling me. How is she doing it?

M D Michigan

ANSWER—The patient should be hospitalized for at least a long enough period to determine the presence of some organic physical disease. From the observations reported one cannot make a diagnosis of malingering. It is suggested that while the patient is being hospitalized the following regimen be instituted: absolute observation twenty-four hours daily, search her bed table and belongings for any drugs or objects that may produce a rise in temperature. This is best done when the patient is taken out of her room on some pretext or other. The temperature should be taken rectally every three hours. Constant, diligent search should be made for evidence of Malta fever abscess formation sinus disease and low grade pyelitis cystitis or kidney disease. She may have to be hospitalized for at least four weeks or more. If and when her method is determined the entire mechanism of the behavior must be explained to her. It is unusual for a girl 15 years of age to refuse to go to school. Organic physical disease should not be overlooked.

EOSINOPHILIA

To the Editor—I have recently discovered a decided eosinophilia in two members of the same family. In both of these cases the causes usually given for an eosinophilia can be ruled out. Might this be a familial characteristic? Could it be due to some chronic streptococcal focus of infection? Counts in the two cases range between 9 and 15 per cent. The reason for this query is more than mere medical curiosity, since in one of the cases I am trying to make a diagnosis of an obscure chronic condition. Any lead you may give me will be greatly appreciated.

HAROLD C MILLER M D Eglon W Va

ANSWER—To answer the specific questions first it is not likely that this is a familial characteristic. Certain isolated instances of unexplained eosinophilia have been reported but it has not been observed as a familial trait. Likewise chronic streptococcal infection is a most unlikely cause. As a general rule the eosinophils diminish or disappear in the presence of infection or intoxication and their reappearance is looked on as a favorable sign of recovery.

The question does not state which of the causes of eosinophilia may be ruled out in these cases.

Of the parasitic causes, trichinosis is the most common but it is sometimes forgotten that the eosinophilia may persist for as long as two to three years following the infestation. Less common parasitic diseases encountered in this country are hook-

worm disease and echinococcal disease. Bilharziasis or filariasis is not likely to occur in a native of West Virginia. The ordinary intestinal parasites do not as a rule produce eosinophilia.

Allergic and so called anaphylactoid states are commonly associated with eosinophilia. The most common of these are bronchial asthma and pollen sensitization but the tendency runs through the whole group and any allergic state may be considered a sufficient cause. Urticaria, Quincke's edema, migraine and even dermatographia are often so affected.

Many of the skin diseases provoke eosinophilia. It is frequently associated with psoriasis and many observers have stated that any chronic dermatitis may be the causative factor.

Still more rarely eosinophilia occurs in connection with myelogenous leukemia and an eosinophilic leukemia has been described. Certain drugs, notably those which produce a skin rash have been known to produce it. In a small percentage of cases of Hodgkin's disease and after x-ray treatment eosinophils may appear in relatively large numbers.

SEBACEOUS CYSTS

To the Editor—I have a patient who has used massage cream on his face for years. He is a rancher and is exposed a great deal to the sun and has a light complexion. His face is covered with small and large collections of sebaceous material. However there are no blackheads as these collections of sebaceous material are covered with a thick layer of dead skin. What is the best method to relieve this man of his condition?

M D Texas

ANSWER—In view of the fact that these collections of sebaceous material are covered with a thick layer of dead skin one must assume from the meager description given, that they are probably multiple sebaceous retention cysts (cystic acne?).

Puncture of one of these lesions with a fine knife such as an iris knife, and the expression of the retained secretion should reveal the wormlike sebaceous contents. The cautious use in competent hands of fractional x-rays, 75 roentgens each week for from six to eight doses may be effective in causing resolution of these lesions. Brisk washing with soap and water preceded by contrast compresses of hot and cold water is important treatment. The use of mild sulfur lotions such as *lotion alba* are further adjuncts to therapy. Creams or greasy applications to the face should be prohibited.

OSTEOGENIC SARCOMA

To the Editor—A man aged 50 generally in perfect health recently suffered a mild contusion of the left knee just below the patella. The injury actually occurred about ten days before he came to my office. About three days after the original injury the patient noticed some slight swelling in the knee which extended both above and below the joint. The pain was slight and the movement of the knee was only slightly impaired. He continued his work which was that of a common laborer. About three weeks after this injury the swelling had increased so that at this time the swelling was about twice the size of the normal knee. Roentgenograms were taken and it was discovered that in the distal end of the femur an apparently abnormal condition was present which looked either like osteomyelitis or a bone tumor. Following this a biopsy was done and the diagnosis by a competent pathologist showed it to be an osteosarcoma. Amputation in the upper third of the thigh was done. The patient recovered without subsequent complications. In going over the man's history I find that fourteen or fifteen years ago he was kicked by a mule on this knee. It has never shown any signs of injury or disability of any sort. What in your opinion is the relationship of the sarcomatous condition of this bone to these two injuries? Is it possible or probable that the injury fourteen or fifteen years ago could have any relation to the development of the sarcoma at this late date?

M D Oregon

ANSWER—The exact etiology of osteogenic sarcoma is not definitely established. In a large majority of cases there is a history of previous injury at the site of the lesion, and this fact has led many authorities to believe that trauma may be the exciting cause. Similar injuries are incurred however by countless people without the development of sarcoma. Fractures of the long bones, which are severe and definite local injuries are practically never followed by sarcoma.

Cohnheim's theory is that at some stage in the embryonic development the cell becomes isolated while still possessed of great energy of growth and of great potentiality to reproduce tissue. The cell may lie dormant for years and when stimulated may begin to grow rapidly (quoted from Campbell). Other authors believe that the origin of tumors lies in a profound change in the character of the cells. The majority of physiologists believe that bone is formed by a specially differentiated cell from the mesodermic layer, a mesoblast, whose only function is to form the tissues produced by the evolution of bone.

In the case described it is possible that the injury of fourteen years ago might have produced an alteration in some of the bone cells and that these cells were stimulated by the recent

injury, with the resulting sarcomatous proliferation. Any such theory, however, cannot be scientifically proved in this particular case.

The question of the relationship of malignant neoplasms to previous traumas is of course a subject of tremendous medico-legal importance but it has not yet been definitely established.

HAY FEVER WITH NERVOUSNESS AND INSOMNIA

To the Editor—I should like your advice concerning a case of hay fever. It is rather peculiar and I have not had much success with this patient. He has been troubled since 1925 with hay fever which begins May 20 and ends June 20. He states that he is able to mark the dates on a calendar in that they begin precisely on the specified dates. He lived in Illinois until 1931 when he moved to Pittsburgh. There he was given irradiation to the nose with marked improvement of his condition. In 1935 he moved to Virginia and last May he began to have skin lesions suggesting urticaria with evidence of angioneurotic edema. However he had gotten a shot of 1 cc of poison ivy several days before the eruption and swelling took place. He was given ultraviolet therapy and left for Philadelphia where he was seen by a doctor who made skin tests. Several days ago I repeated the skin tests and the results were as follows:

Bermuda grass	2+	False ragweed	±
Goldenrod	±	June grass	4+
Lamb's quarters	5+	Timothy	3+
Orchard grass	3+	Oat	±
Johnson grass	1+	Chicken feathers	1+

The remainder of the tests were negative. However the chief reason for his visit to me is apparently insomnia. He states that he must exhaust himself physically before he can get any rest. Physical examinations at several places have been relatively negative. I do not get the food reactions obtained in Philadelphia. I suggested a pollen mixture of the positive obtained with injections to begin immediately. Whether or not this will affect his insomnia I do not know. I should like any suggestions that you may care to offer.

M D Virginia

ANSWER—Nervousness and insomnia have been described as among the 'minor allergies' although allergy is to be considered an unusual cause for such symptoms. Presumably other more common causes for insomnia have been ruled out in this case. If one is to assume therefore, that hypersensitivity is the cause for the nervousness and insomnia one must look to other causes than pollen as a source of the trouble since the symptoms are present perennially. While pollen treatment (grasses) should be carefully used this should be done because of the definite hay fever symptoms present.

Regarding the other allergic factors the patient should be protected from feathers and possibly house dust by covering the pillows and mattresses in the room with a rubberized casing that is impervious to the finest dust. This should be constructed so that it is almost air tight. It is possible that the insomnia may be induced by stuffiness of the nose from the inhalation of allergens. (No mention is made whether the patient has perennial nasal symptoms.)

Since the skin tests with foods are reported negative it would be advisable to continue the study by the use of elimination diets and the determination of the leukocyte reaction after certain foods as milk, wheat and eggs. Literature on the subject of allergic study by elimination diets may be obtained in Albert H. Rowe's 'Food Allergy' (Philadelphia: Lea & Febiger, 1931). The rationale and technique of the leukopenic index studies may be found in Warren T. Vaughan's recent publications on the subject (*J. Allergy* 5: 601 [Sept.] 6: 78 [Nov.] 1934; 6: 421 [July] 1935; *J. Lab. & Clin. Med.* 21: 1278 [Sept.] 1936).

PLAYING WIND INSTRUMENTS IN PULMONARY TUBERCULOSIS

To the Editor—A patient who has been under treatment for pulmonary tuberculosis for the last three or four years has taken pneumothorax for the last two and one-half years and the condition now seems to be well arrested. He would like to play some wind instrument such as the saxophone and would like your opinion as to the advisability of his doing so. I understand that some sanatoriums have musical organizations including reed instruments.

JOSEPH O. RUDE, M.D., Petersburg, Alaska

ANSWER—The nature and extent of the pulmonary lesion before artificial pneumothorax was instituted will influence the decision in this case. If it was a primary lesion in the pneumonic stage and is now well under control almost any activity could be undertaken. On the other hand if it was a secondary or reinfection type of lesion that showed evidence of progressiveness and cavities had formed the playing of a wind instrument should be discouraged.

While it is true that, in occasional institutions for the tuberculous orchestras and bands have been organized such activities on the part of patients with pulmonary tuberculosis are not generally recommended. If the musicians are selected from patients who have extrapulmonary disease such as that of the

bones and joints there could be no objection provided the general health would permit of such activities. It is true that almost any clinician who deals largely with tuberculosis can cite instances in which persons with pulmonary disease have since played wind instruments extensively or have actually done considerable singing over the radio while the diseased lung was collapsed by artificial pneumothorax and even after it has reexpanded.

After all the main factor in the control of the tuberculous lesion is immobilization or minimum activity of the involved organ. While the patient's lesion is well arrested by artificial pneumothorax there is the possibility that lesions are present in the contralateral lung which have not yet reached such proportions as to cast shadows on the x-ray film. These lesions may remain under control because of the natural defense mechanism of the body and never become clinically significant or roentgenologically demonstrable but it would not seem wise to recommend activities that would require unnecessary use of the lung tissue. It would appear far safer to advise the patient against the use of any wind instrument.

VACCINATIONS FOR ORIENT

To the Editor—A patient of mine contemplates a trip to Japan and China starting in August and would like preventive inoculations such as are available for whatever infections she might encounter on such a journey. I have already started typhoid paratyphoid inoculations and shall revaccinate her against smallpox. Could you inform me as to what other preventive inoculations are available for what might be encountered in Japan and China?

C. WENTWORTH HOYT, M.D., Hingham, Mass.

ANSWER—No other preventive inoculations are customary for adults. If revaccination against smallpox is not immediately successful it should be repeated several times until there is a high degree of probability that immunity actually exists. Since most of the health hazards in the Orient arise from contaminated food and water the patient should be instructed to eat only freshly cooked foods and to drink only boiled water. Raw fruits and vegetables are particularly to be avoided.

TOXICITY OF VARNISH FOR BEER BARRELS

To the Editor—I have under my care a man aged 42 who is employed in a brewery. His job for the past two months for six hours daily five days a week has consisted of working in a beer standard (a wooden enclosed container holding twenty-two barrels of beer). He and another man varnish these standards and then burn the varnish in with blow torches. The only means of ventilation is a ventilator about 3 inches in diameter set in the roof of the standard. This is inadequate and the fumes very rapidly become thick so that after ten minutes of the work they must lie down on the floor for fresher air. The varnish is supposed to be thinned with pure grain alcohol but lately they have been given denatured alcohol to use which he has been told will not do them any harm from the fumes liberated. Lately he finds that he has been gagging easily is dyspneic on slight exertion coughs up blood streaked material in the morning perspires freely is quite weak and has developed pain and tenderness to the left of the sternum. He has also lost 5 pounds (2.3 kg.) in three months. General physical examination is negative. I should like to know what harm working in the conditions described can do to him and whether pure grain alcohol would be a safer diluent for the varnish. I would appreciate an early answer in your column.

M. D. Minnesota

ANSWER—Unfortunately the term "varnish" does not represent any one substance of fixed consistency. There are many classes of varnish with highly diversified ingredients chiefly natural and synthetic gums as the solid portion of the varnish which in turn are dissolved in or thinned by an even greater diversity of liquid agents. By way of example may be cited the constituents of one type of varnish: phthalic anhydride, fatty acids, glycerin, rosin, tung oil, hydrogenated naphtha, petroleum naphtha, xylene and butanol. Other types of varnishes contain comparable agents with respect to toxicity and may instead contain toluene and rarely benzene.

Compared with most of these substances less harm may be expected from either pure grain alcohol or some classes of denatured alcohol. If these standards are in fact enclosed as described the combined vapors from the constituents of almost any varnish are likely to be sufficiently concentrated to be dangerous. Furthermore the use of blow torches as described for burning the varnish into the wood may be expected to give rise to additional harmful substances and particularly irritants to the eyes, mucous membrane and skin in case high temperatures are utilized such as may break down the solid constituents of varnishes. It is not believed that the mere changing of the thinning solution will be adequate for righting this situation. From the description of the operation provided in the query it may be desirable that positive pressure respirators should be worn at all times during the varnishing procedure. The clinical manifestations indicated are of a type commonly asso-

ciated with mixed toxic vapors. If any substantial percentage of benzene, toluene and xylene or solvent naphtha is present as an ingredient and has produced harmful results this may be shown in a leukopenia together with an anemia. In any event, a careful blood examination should be made.

INFECTIOUSNESS OF SYPHILIS—INHERITANCE OF COLOR BLINDNESS

To the Editor—I am frequently asked by the employer of a syphilitic patient in whom the infection is newly acquired but untreated when it is safe for him to return to work and of course associate with and eat with other employees. Granting that treatment is started I have advised the employer that it is safer for the associate workers for the patient to be given about three injections of neosarsphenamine before he is allowed to return to work and where the work consists of handling food as in a restaurant about six injections. I realize that many factors enter into these cases but my question concerns the average case of early syphilis that is found in a clinic where most of the patients are WPA workers. I would appreciate your opinion as to the wisest course to follow for all concerned. 2 If the mother is color blind does it necessarily follow that all her children will be color blind?

M D Virginia

ANSWER—1 The chances of acquiring syphilis from ordinary association are recognized as being remote. The disease is transmitted most frequently in the serous discharges from primary or secondary lesions. The chances therefore of a patient with early primary syphilis transmitting the infection through food are not great. No arbitrary number of injections, however, can insure the noninfectiousness of the disease. It is probable that the proposed number of injections would be adequate to prevent any chance infection of healthy individuals.

2 No

POTASSIUM CHLORATE IN DENTIFRICES

To the Editor—What are the names of the dentifrices and gargles that contain potassium chlorate?

M D Massachusetts

ANSWER—This is a partial list of products which have been found to contain potassium chlorate:

Alkalol the Alkalol Company Taunton Mass
Anti-Vinzing Remco Products Company Fairmont W Va
Dr Cates Cato Tooth Paste Cato Chemical Company St. Louis
Gingasoil Gingasol Laboratories Inc. Winner S D
King's Ceko Dental Paste C G King & Co. Providence R I
Lorty Antiseptic Tooth Paste B F Allen Company New York
Pebecco Tooth Paste Lehn & Fink Inc. Bloomfield N J
Potaska F M Pease & Son Lee Mass
Pyo-Rem and Pyo-Rem Dental Cream Pyo-Rem Chemical Company Inc. Los Angeles
Tonsiline Tonsiline Company Canton Ohio

These nonproprietary preparations also contain it:

Gargle of Potassium Chlorate with Iron N F VI
Tablets of Potassium Chlorate N F VI
Camphor Potassium Chlorate and Belladonna Powders P R B II
Troches of Potassium Chlorate P R B II

SODIUM CHLORIDE INTAKE IN DIABETES

To the Editor—How and where could I find some information regarding increased sodium chloride intake in diabetes and its effect on the disease and the patient?

M D Ohio

ANSWER—Recent reports by Glass and Beilless, McQuarrie, Thompson and Anderson, McLain and Wilder, and others of the effect of increased intake of sodium chloride in diabetes are reviewed and references given in editorial articles 'Diseases of Metabolism and Nutrition' by Wilder and Wilbur (*Arch. Int. Med.* 59:342 [Feb.] 1937, 57:429 [Feb.] 1936). Another study of the subject has appeared lately from D. Adlersberg and M. Wachstein (Pankreas und Kochsalzstoffwechsel [Experimentelle und klinische Untersuchungen], *Klin. Wchnschr.* 16:85 [Jan. 16] 1937).

ARTIFICIAL SCARLET FEVER IMMUNIZATION

To the Editor—Please evaluate the present status of active artificial immunization against scarlet fever. Has immunization with scarlet fever streptococcus toxin been accepted by conservative authorities as a sound procedure suited to general application? Is it felt that there is risk of cardiac damage in children from the administration of scarlet fever toxin for purposes of immunization?

PAUL J. BROWN, M.D., Terre Haute, Ind.

ANSWER—Inoculation with scarlet fever toxin for the purpose of active immunization against scarlet fever is a procedure that has been accepted by most contagious disease hospitals. The method is used also in many general hospitals to protect student nurses and for large numbers of children housed in various institutions.

Health authorities in Milwaukee and in Gary, Ind., are enthusiastic in their approval of the Dick method for active

immunization against scarlet fever. Private physicians often hesitate to recommend inoculations of scarlet fever toxin because of their fear of unpleasant reactions. If scarlet fever toxin is injected intracutaneously instead of subcutaneously, it is reported that satisfactory results are secured with smaller doses of toxin and no constitutional symptoms occur.

The possibility of cardiac damage as a result of the administration of scarlet fever toxin is seldom considered.

Scarlet fever toxin injections do not establish immunity to streptococcal infections.

ALTERNATIVE FOR MAN AND DOGS

To the Editor—A veterinary surgeon showed me an alternative and reconstructive veterinary preparation which he said was excellent for dogs consisting of mercuric iodide, sodium iodide and sodium cacodylate. Would this be equally effective in man? Can you suggest a prescription in appropriate dosage for human patients and a vehicle that would be pleasant?

J. B. H. Waring, M.D., Wilmington, Ohio

ANSWER—There is no incompatibility in the ingredients and the following prescription might be suggested as possibly as pleasant a method of administration as might be devised:

R Mercuric iodide	0.075 Gm
Sodium cacodylate	1.5 Cm
Sodium iodide	100 Gm
Distilled water	200 cc
Syrup of acacia	600 cc
Syrup of glycyrrhiza	to make 1200 cc

Label: One teaspoonful in milk three times a day after meals.

ANTIRABIC TREATMENT AFTER DOG BITE

To the Editor—A child aged 2½ was bitten by a dog on the nose and face. The wounds were deep and extensive. The dog was not thought to be mad but the veterinarian who examined the dog would not make a positive statement to that effect. My advice was that since there was some doubt the child should be treated as though the dog were rabid. The wounds were cauterized with fuming nitric acid and dressed and the first dose of the serum was given. The injections were continued for six consecutive days. On the seventh day the veterinarian reported that the dog positively was not mad. I then stopped the treatment. Was I justified in my action or should I have carried the full fourteen doses to completion? I am unable to find any comment on this particular phase of the treatment in any of the literature.

M D Louisiana

ANSWER—On the assumption that the veterinarian's report is correct there of course would be no point in continuing the injections. However, the period is entirely too short a time in which to rule out absolutely the possibility of rabies. All possibilities considered, therefore, the maximum safety would have been attained by completing the prescribed course of treatment.

NATURE OF WORMS IN DOGS AND DANGER TO MAN

To the Editor—My dog is infested with worms as proved by the examination of a veterinarian. He found the adult worms or the ova of the roundworm tapeworm and hookworm. Are these worms identical with the roundworm tapeworm and hookworm found in man? Is there any danger of human infestation from such a dog?

M D Iowa

ANSWER—Intestinal worm parasites that infest dogs are not identical with those found in man. Observations made by many veterinarians tend to show that there is no danger of contaminating human beings with canine parasites where good hygiene prevails. However, for the protection of infants and young children, veterinarians advise keeping canine pets free from parasites.

INHERITANCE OF BLUE EYES

To the Editor—If both mother and father have blue eyes does it necessarily follow that all their children will have blue eyes? Are there any cases on record in which this is not the case?

M D Virginia

ANSWER—Genetically speaking, blue eyes are blue because they lack pigment in the front of the iris. If in the eyes brown pigment is present even if it cannot be detected except with the aid of a microscope such eyes are genetically "brown." It is difficult for any but an expert to distinguish blue eyes from some of the lighter types of brown eyes such as grays or greens. If both parents have blue eyes in the genetic sense they can have only blue eyed children. It would be unwise for persons other than experts to attempt diagnosis of blue eyes in cases in which apparent exceptions to the rule occur.

TREATMENT OF YAWS AND PELLAGRA

To the Editor—Kindly advise me whether bismuth compounds and/or neosarsphenamine would be indicated in the treatment of yaws? Would bismuth compounds and/or neosarsphenamine be indicated in the treatment of pellagra?

D D S California

ANSWER—Bismuth compounds and neosarsphenamine are indicated in the treatment of yaws but not in pellagra.

Book Notices

The Thyroid and Its Diseases By J H Means MD Jackson Professor of Clinical Medicine Harvard University Boston Being an Account Based In Large Measure on the Experience Gained in the Thyroid Clinic of the Massachusetts General Hospital Cloth Pn e \$6 Pp 602 with 73 Illustrations Philadelphia Montreal & London J B Lippincott Company 1937

Although the preface to this monograph states that it is in no sense an encyclopedic treatise on the subject and represents only the personal experiences of a considerable group of workers in a single thyroid clinic (that of the Massachusetts General Hospital), this book cannot be said to lack in completeness. The motive behind the work of the clinic has always been twofold to care for the patient in the best possible way and to learn from him something new about his disease. These purposes, of course, coincide perfectly with the highest type of medical practice and clinical research. The initial fundamental discussion of the thyroid and its diseases takes up about one fourth of the book. The gross and microscopic anatomy of the gland, the chemical nature and actions of the hormone so far as known, the relation of the thyroid itself to other endocrine glands and the pathology are considered in detail. The general symptomatology of disturbances of the thyroid and the methods of examination for thyroid disease are perhaps especially useful to medical students and to those physicians who have need to refresh themselves on the present methods of approach to thyroid disease. Specific disorders are considered in a number of chapters on simple goiter, myxedema, toxic goiter, nodular goiter, malignant goiter and thyroiditis. The grouping of the subjects is satisfactory and each chapter is closed with a brief summary and bibliography, which includes probably all the more important publications on that particular subject. The surgery of toxic goiter includes no detailed description of surgical technique but contains many points of importance for the medical and surgical preoperative and post-operative care, the operation itself and the anesthesia. In the final chapter, on fact and fancy in matters thyroid (a term which the author does not like very well), some luxury is allowed in attempting to forecast some of the future lines along

which thyroid investigations may proceed. This is a satisfactory addition and might well even be expanded in the future. Certainly no physician dealing with thyroid diseases can afford to be without this monograph.

The Little Things in Life. The Vitamins, Hormones and Other Minute Essentials for Health. By Barnett Sure, Ph.D., Professor of Agricultural Chemistry in the University of Arkansas. Cloth. Price \$2.50. Pp. 340. New York & London: D. Appleton Century Company Incorporated, 1937.

The late Lafayette B. Mendel of Yale often referred to certain food substances such as vitamins and organic salts as "the little things" in nutrition. The author has made use of the same thought in the title of the present volume. The subject matter comprises a description of the vitamins, hormones and other substances which in small amounts, are essential to life. The book is written in nontechnical terms, primarily for the public. A glossary of medical terms is appended. In general the information provided is sound and technically correct. The author presents an interesting historical account of the modern developments in the field of vitamins. A long chapter is devoted to a description of the use of vitamin preparations in various ailments. The author concludes that considerably more clinical evidence will have to be available as a guide to the medical practitioner before he will know definitely the value of vitamin preparations in the treatment of diseases other than the well known deficiency diseases. Tables of the vitamin content of foods are included, but these are of the older type which denote the relative amounts of the vitamins present by plus and minus signs. The chapters on hormones and on topics other than the vitamins are not as authoritative as they might be. The chapter on allergy appears to be inadequate for the importance of this subject and in relation to the other topics in the book. There are probably many more persons who are treated for hypersensitivity toward some substances than are treated for vitamin deficiency. On page 119 goat milk is erroneously reported to be much more digestible than cow's milk. The author acknowledges the assistance of Professor Hastings of the English Department of the University of Arkansas for help in editing a great portion of the manuscript. One wonders if some of the definitions presented in the glossary have been given as careful attention as the greater part of the text. Acidosis on page 323 is defined as "an acidic state of the blood and tissues symptomatic of some other disturbance in the body which upsets the normal acid-alkali balance." The book on the whole is well organized about the author's central theme, which is "Since they can make or break the human organisms, the little things in life actually are the big things in life."

Diseases of the Newborn. By Abraham Tow, M.D., Adjunct Professor of Pediatrics, New York Polyclinic Hospital and Postgraduate Medical School. Cloth. Price \$6.50. Pp. 477 with 53 illustrations. New York: Oxford University Press, 1937.

Unlike the many textbooks written about certain other medical subjects there has been a real paucity of those confining their subject matter to diseases of the new-born. There has been a tremendous increase in medical interest in the new-born during the past ten years owing to a considerable extent to the fact that the pediatrician has assumed more and more the control of the nursery services, that is, the infant from the time of birth. As a result a voluminous literature has developed. The author states that the volume is an attempt to organize this material and to present it in such a fashion that it will be of service to the general practitioner, the obstetrician and the pediatrician. The author has had years of experience in the new-born service at the New York Polyclinic Hospital and so in discussing a controversial subject he expresses his opinions in an attempt to clarify the matter. These opinions are well balanced and logical and coincide with the ideas of the majority of pediatricians. The textbook is concise yet complete and the style of writing makes for easy and interesting reading. It is well illustrated and on good paper. The table of contents and index are detailed so that a small item can be looked up quickly. An excellent and detailed bibliography is appended to each chapter. The discussion is confined to the first month of life except where it is necessary to extend it for purposes of clarification. The book includes, besides diseases of the new-born, a chapter on general con-

siderations of the normal new-born, another on the premature infant and still another on infant feeding during the first month. There is a discussion of the hypoglycemic cyanosis and convulsions of infants born of diabetic mothers and its treatment, a subject only recently creeping into pediatric literature. The author plainly, firmly and logically states his position on controversial points such as the treatment of intracranial hemorrhage.

Funktionelle Pathologie. Eine klinische Sammlung von Ergebnissen und Anschauungen einer Arbeitsrichtung. Von Dr. Gustav von Bergmann, ordentl. Professor der Inneren Medizin und Direktor der II Med. Universitätsklinik Berlin. Second edition. Paper. Price 25 marks. Pp. 547 with 73 illustrations. Berlin: Julius Springer, 1936.

This is the revision of a book which early established itself as a useful volume in this field. It begins with a chapter entitled "Klinische Reformation," in which the author points out that conditions have changed considerably in Germany and that the whole future depends on keeping the German people in health—this to be assumed as a holy task. The book is a collection of available data dealing with functional pathology based on studies of the available periodical literature. As with most German books, the references are frequently to medical preparations which have no standing and no use in the United States. The final chapter is largely concerned with psychic effects on human function, the volume concluding with emphasis on the fact that modern medicine depends on the consideration of the human being invariably as a social organism. The book is a beautiful illustration of the great difficulty under which the modern German scientist labors to steer a suitable course between scientific and political influences.

Accidents and Their Prevention. By H. M. Vernon, M.A., M.D., Member of the Technical Advisory Board, National Institute of Industrial Psychology, London. Cloth. Price \$5. Pp. 336 with 61 illustrations. New York: Macmillan Company, Cambridge University Press (n.d.).

This book should be read by all who are interested in the subject of safety, since it presents a comprehensive study of accidents of many kinds on the road, at home, at work, at play, with an account of preventive methods already used and suggestions for further methods of avoiding accidents. Numerous charts and graphs furnish clear cut analyses of important factors in accidents. A particularly interesting feature is that comparison of accidents in various countries permits a better analysis of accident causes and the results of different methods of prevention. A discussion of susceptibility to accidents is particularly valuable. It is clearly shown that a small percentage of people have most of the accidents and that psychological tests for accident proneness have definite value. These tests are not always conclusive, however, so it is advisable to keep accurate records of all accidents, even the most trivial. These records are probably the best means of identifying the accident prone individual. A relationship between physical condition of an individual and accident proneness is important, since some easily determined conditions, such as high blood pressure, impaired vision, obesity and alcoholic indulgence, are associated with a high accident rate. The discussion of traffic accidents is unusually comprehensive and is important to all who are interested in traffic safety. The value of education in preventing accidents is shown by the decreasing rate among school children compared to the increase among adult pedestrians. The author closes with a statement that from 50 to 90 per cent of accidents are preventable by legal control or education.

Physicians and Medical Care. By Esther Lucile Brown, Department of Statistics, Russell Sage Foundation. Boards. Price 75 cents. Pp. 202. New York: Russell Sage Foundation, 1937.

This is a helpful compilation of information not readily available in any other single work. The survey of medical education traces stages in its evolution, describes the work of the American Medical Association and calls attention to the weakness of the present curriculum, with regard to obstetrics, psychiatry and medical economics. The growth of graduate education in recent years is emphasized and the recent provisions for certification of specialists are described. There is a tendency in the discussion of graduate work for practicing physicians to follow previous writers in ignoring the fact, which is briefly

mentioned, however, that such education in organized form is only twenty years old and can scarcely be expected to have reached and benefited all practicing physicians. There is a brief history of the growth and work of the various councils of the American Medical Association, and the conventional criticism that "Its Journal has appeared to be opposed to many honest experiments that were being undertaken by groups of physicians and foundations in the interest of more extensive medical service." There is no recognition of the fact that the various branches of the Association are conducting, under principles laid down by the House of Delegates, more experiments than all the foundations and similar organizations in existence. A treatment of the number of physicians and the demand for their services makes use of some unreliable statistics of the Committee on the Costs of Medical Care, although the writer quotes from publications of the Bureau of Medical Economics in which these errors are corrected. It is perhaps unfair to criticize the position, which has been so generally adopted by others, that the distribution of physicians according to the population of the towns in which they are located measures the availability of medical service. The material of the Committee on the Costs of Medical Care which is used in describing groups has also been shown to be inaccurate. There is a description of some of the plans for low income groups developed by medical societies, and the book closes with at least a partial endorsement of compulsory health insurance, in which the position of the American College of Surgeons, the Michigan State Medical Society and the California Medical Association is somewhat inaccurately reported. In spite of these defects, the book represents a decided improvement over most of the writings on medical matters issued by foundations.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Die Hirnkammerformen bei Hirntumoren. Von Dr. Otto Dyes Dozent für Röntgenheilkunde Würzburg. Fortschritte auf dem Gebiete der Röntgenstrahlen Ergänzungsband LII. Herausgegeben von Prof. Grassley. Iaper. Price 16 marks. Pp 79 with 105 illustrations. Leipzig Georg Thieme 1937.

This brief monograph deals with the shape of the cerebral ventricles as affected by tumors of the brain. The ventricles were visualized by roentgenograms after they were filled with air, a procedure which the author, in accordance with German usage, persists in calling the Bingel-Dandy method although priority for both encephalography and ventriculography seems to belong clearly to Dandy. After a preliminary chapter on the normal form of the ventricles, which follows closely the work of Torkildsen, the various alterations that are caused by tumors of the brain are clearly outlined and numerous illustrative cases from the clinic of Tonnus are reported. Although there is nothing new in this material, dealing as it does with matters familiar to the workers in all the large clinics of this country and to every roentgenologist, the presentation is clear and systematic and the work should be useful to roentgenologists and neurosurgeons.

Medicolegal Cases. Abstracts of Court Decisions of Medicolegal Interest 1931-1935. Compiled by the Bureau of Legal Medicine and Legislation American Medical Association. Cloth. Price \$5.50. Pp 888. Chicago American Medical Association 1936.

Abstracts of important court decisions of medicolegal interest have been published in THE JOURNAL since about 1900. Some years ago, in response to recurrent demands for the republication of the abstracts in book form, an initial volume was prepared embodying abstracts that had appeared in THE JOURNAL during the calendar years 1926 to 1930. The present volume contains the abstracts that were published during the calendar years 1931-1935 inclusive. It constitutes, as did its predecessor, a mine of medicolegal information of civil and criminal interest. A comprehensive seventy-three page index makes readily available all the important points in the approximate 900 court cases abstracted. Anesthetics, autopsies, compensation of physicians, dental practice acts, hospitals, insanity, insurance, malpractice, medical practice acts, narcotics, optometry practice acts, pharmacy practice acts, privileged communications, trauma and workmen's compensation acts are a few of the 375 principal references found in the index. Physicians and others interested in solving medicolegal problems will find this book a most useful addition to their reference libraries.

Human Physiology. A Practical Course. By C. G. Douglas. M.C. D.M. and J. G. Priestley. M.C. D.M. Second edition. Cloth. Price \$4.25. Pp 229 with 32 illustrations. New York & London Oxford University Press 1937.

This book is intended mainly for the use of medical students in courses in physiology, it gives detailed directions for various experiments that can be done on human subjects. Unfortunately, many of these experiments are of a kind which, in the United States, would be reserved for courses in physiologic chemistry. If one leaves these out of account there remains little that will be of help to American teachers of physical physiology excepting those already addicted to the use of Douglas bags and bicycle ergometers. The nervous systems and special senses are omitted, as the authors point out in their preface, but this is a field in which many medical students particularly need more experience. So, for instance it would be interesting to apply simple tests that would reveal, even if they did not diagnose exactly, the disturbed mental state of a person in an anoxia chamber or during voluntary hyperpnea. The book contains some instructive figures and useful references to recent physiologic literature, it should be a welcome addition to a physiologic library.

Practical Orthoptics in the Treatment of Squint. By Keith Lyle. M.A. M.D. M.Chir. Assistant Surgeon Royal Westminster Ophthalmic Hospital London and Sybil Jackson Senior Orthoptist Royal Westminster Ophthalmic Hospital London. Foreword by Charles Leonard Crompton. M.A. M.D. M.R.C.P. Surgeon Royal Westminster Ophthalmic Hospital London. Cloth. Price 12s 6d. Pp 211 with 68 illustrations. London H. K. Lewis & Co. Ltd. 1937.

In England there is an Orthoptic Board, which regulates the training and qualification of nonmedical orthopticians, who are pledged to work under the guidance and supervision of ophthalmologists. These orthopticians are given a year of training, at the end of which time they must satisfy the examiners of the board as to their efficiency. Kyle and Jackson have written a practical manual for them, in which they have largely avoided theoretical discussions as well as controversial subjects. The result is one of the clearest and simplest expositions of the subject. The necessary instruments are illustrated and clearly described in this book, together with the indications for the proper time and method of usage. The management of various types of squint is discussed at some length, but simply and clearly. Cases are frequently cited to illustrate the points. The book can be read advantageously by all ophthalmologists as well as by orthopticians.

Eugenical Sterilization. A Reorientation of the Problem. By The Committee of the American Neurological Association for the Investigation of Eugenical Sterilization. Abraham Myerson M.D. and others. Cloth. Price \$3. Pp 211 with 8 illustrations. New York Macmillan Company 1936.

A special committee appointed by the American Neurological Association developed this report, aided by a grant from the Carnegie Foundation. The report evaluates critically the whole question of inheritance of mental diseases, feeble-mindedness, epilepsy and crime, and derives from its study certain recommendations of importance. The committee does not consider that our knowledge of human eugenics is sufficient to warrant sterilization of people who themselves are normal in order to prevent the appearance of such conditions in their descendants. It does not consider that there is at present any sound scientific basis for sterilization because of immorality or character defects. It suggests that any laws concerning sterilization passed in the United States should be voluntary and regulatory rather than compulsory, moreover, that these laws should be applicable not only to patients in such institutions but also to those in private institutions and those at large in the community. Selective sterilization, it is felt, should be considered in cases of the following diseases: (1) Huntington's chorea, hereditary optic atrophy, familial cases of Friedreich's ataxia, and certain other disabling degenerative diseases recognized to be hereditary, (2) feeble-mindedness of familial type, (3) dementia praecox (schizophrenia), (4) manic-depressive psychosis, and (5) epilepsy. It is obvious that much additional research is necessary. The book concludes with an excellent bibliography and an index.

Autopsy Diagnosis and Technique A Manual for Medical Students Practitioners Pathologists and Coroners' Physicians By Otto Saphir M.D. Chairman Nelson Morris Institute for Medical Research Chicago Foreword by Ludwig Hektoen M.D. Cloth Price \$5 Pp 342 with 65 Illustrations New York & London Paul B Hoeber Inc 1937

Modern medicine has grown largely on the basis of knowledge acquired in postmortem work. The student in the medical school sees postmortem examinations made by competent pathologists, but only a few learn the actual technic of the necropsy. When the physician goes into practice, however, he may actually be called on to make a postmortem examination. In any event, it may be necessary for him to comment expertly on the results of such examinations. At various times, articles have appeared in periodical medical literature describing the technic of the postmortem examination, notably one by E. R. Leacock in *THE JOURNAL* some years ago. In this manual the technic is modified from that of Rokitsansky. The outline is presented as a guide to the method of making the examination and of interpreting the gross appearances observed at that time. The book is well written, is profusely illustrated, and is supplemented by excellent charts and tables and a fine index.

Federal and State Control of Milk Prices By James A. Tobey Jr. P.H. Member of the New York District of Columbia and United States Supreme Court Bars. Cloth Price \$2 Pp 42 Chicago International Association of Milk Dealers 1937

This little book appears as a companion to the author's "The Legal Aspects of Milk Control," published in 1936. The earlier work was a digest of laws regulating milk and its products, and the present volume is a review of the constitutional status of laws fixing prices and regulating the production and distribution of milk. Most of this type of legislation has arisen since 1933, especially under the Agricultural Adjustment Act. The author devotes an entire chapter to an outline of the New York law. The consensus of milk dealers in New York is that the price control of milk in that state has not abolished price cutting, has not benefited either the consumer or the dealer, and is not uniformly enforceable. Perhaps as a consequence of this attitude the emergency milk control law in New York was not reenacted in 1937. The milk control laws in other states are discussed briefly in comparison with the New York laws. There is appended a table of cases that were tried before federal and state courts.

Prognosis Volume II Cloth Price 10s 6d Pp 410 London The Lancet Limited 1937

This is a continuation in book form of the series of articles on prognosis which have appeared in the *Lancet*. In this volume, among other subjects, certain acute and chronic infectious diseases of the bones and joints, some digestive disorders, and diseases of the ear, nose and throat and of the respiratory tract are discussed from the standpoint of their immediate and late prognosis. It is obvious that the outlook in most diseases depends on a large number of factors, including the age and state of the patient, the stage of the disease and the treatment. These factors are considered in most of the brief descriptions of the various disorders. They may be helpful to some clinicians, but the vast majority of experienced practitioners find a much more reliable index in the relatively impalpable factors absorbed from their own past experience.

The Larynx and Its Diseases By Chevalier Jackson M.D. Sc.D. LL.D. Professor of Bronchology and Esophagology Temple University Philadelphia and Chevalier L. Jackson A.B. M.D. M.Sc. Professor of Clinical Bronchology and Esophagology Temple University Philadelphia. Cloth Price \$8 Pp 5.5 with 221 Illustrations Philadelphia & London W. B. Saunders Company 1937

A book of this type on the clinical aspects of diseases of the larynx has long been needed. In spite of the authors' implied apology for the literary structure, it is simply written and easily read, the only obvious criticism of this aspect is the unnecessarily frequent use of "very." Following the discussion of the anatomy and physiology of the larynx and general considerations of laryngeal disease and anomalies there are excellent discussions of injuries, inflammations and tumors, helpfully divided into chapters, to which access is easily had through the table of contents or the adequate index. The illustrations, largely from the authors' own experience, are excellent and

add immeasurably to the volume. This book would seem to be invaluable to any one who might wish to approach the larynx from either a diagnostic or a manipulative angle.

British Masters of Medicine Edited by Sir D. Arcy Power K.B.E. FRCS F.S.A. Consulting Surgeon and Archivist to St. Bartholomew's Hospital London. Cloth Price \$3 Pp 242 with 34 Illustrations Baltimore William Wood & Company 1936

This is a collection of essays that appeared originally in the *Medical Press and Circular*. The book comes with multiple authorship, each of the great British masters being discussed by a current writer attached to the institutions made famous by those whose biographies are presented. Thus the reader will find available fine brief biographies of the great figures whose names have become eponyms, including Harvey, Sydenham, Pott, Jenner and Bright. The qualification of Dr. Power as an editor insures the reader of an accurate and interesting volume. The life of Osler is presented in brief by Miss Reid.

Leitfaden der Blutmorphologie Manual of Blood Morphology. Précis de morphologie sanguine. Von Dr. Par. Lydia Schudel. Boards. Price 6.80 marks. Pp 45 with 13 Illustrations. Leipzig Georg Thieme 1936

This brief manual presents in English, German and French brief descriptions of the various formed elements of the blood, associated with excellent colored plates. The manual should be most useful to laboratory workers everywhere.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Life Insurance Streptococcic Septicemia in Relation to Trauma and Preexisting Splenic Anemia—The plaintiffs were beneficiaries under a policy of life insurance issued by the defendant insurance company, whereby it promised to pay double indemnity if the insured's death resulted from bodily injuries, effected directly and independently of all other causes through external, violent and accidental means, and not, directly or indirectly, from diseases in any form. On March 2, 1934, the insured, who had "splenic anemia and pseudo leukemia" accidentally injured his left hand, sustaining an abrasion about the size of a dime. His family physician applied mercurochrome and bandaged the hand, and repeated the procedure the next day. On March 4 he was taken to a hospital. There it was observed that he was anemic, that the abrasion had become inflamed and swollen, and that there was a large red streak extending from his hand upward on his arm. He complained of considerable pain in his left arm and hand. His temperature, which was 101 degrees Fahrenheit on admission, rose to 105 degrees before he died, March 10. The insurance company paid the face value of the policy but refused to pay double indemnity. The plaintiffs, the beneficiaries, thereupon brought suit. From a judgment in favor of the plaintiffs the insurance company appealed to the Supreme Court of Louisiana.

The record showed that "splenic anemia and pseudo leukemia" is a serious blood disease, which lowers the resistance of the individual to infection. The physician who made the first examination of the insured's blood, Dec. 16, 1933 testified that at that time he believed that the chronic blood disease would eventually be fatal but he could not say whether the expectancy of life would be several months or several years. Three expert medical witnesses testified that streptococcic septicemia or "blood poisoning" resulting from a streptococcic infection of the hand, caused the insured's death. The insured's family physician testified that the streptococcic septicemia had hastened the insured's death. An expert medical witness for the insurance company, however, testified that he was unable to affirm or deny that the insured died of streptococcic septicemia because a microscopic examination of a culture of the insured's blood in order to isolate the streptococcic germ, had not been made. The mortality rate in streptococcic septicemia, it was agreed, even in normal and healthy persons, is high.

The Supreme Court, in deciding that the plaintiffs had proved by a preponderance of the evidence that the insured's death

had resulted from external, violent and accidental causes, independent of all other causes including diseases in any form, relied on, among other cases, *Illinois Commercial Men's Ass'n v Parks* (C C A) 179 F 794, wherein the court said

The phrase resulting directly, independently and exclusively in death' refers to the efficient or as some courts speak of it the predominant cause of death at the time it occurs

The provision in the policy that death must not result "directly or indirectly, from diseases in any form" had no particular significance, as its only purpose was to emphasize the preceding language of the policy, that death must result from "bodily injuries, effected directly and independently of all other causes through external, violent and accidental means" The court admitted that numerous court decisions hold that where death results from an accidental injury and a preexisting disease or infirmity acting together, recovery is not allowed, but in those cases the accidents complained of would not ordinarily have produced death without the intervention of disease In the instant case, said the court, there was an accidental injury, the history and clinical record showed that streptococcal septicemia resulted from that injury, and the insured's death was typical of streptococcal septicemia Under those circumstances, the insured's death would naturally be expected to occur even though he had no preexisting bodily infirmity or blood disorder The court concluded that the septicemia and not the chronic blood disease had caused the insured's death

Accordingly, the Supreme Court affirmed the judgment in favor of the plaintiffs *De Bleur v Travelers Ins Co (La)*, 170 So 14

Accident Insurance Restrictions on Insurer's Right to Autopsy—The defendant insurance company agreed to pay certain benefits to Hemrich or his beneficiary for 'loss resulting, directly and independently of all other causes from bodily injuries sustained and effected solely through accidental means' Hemrich fell, fracturing the lower end of the fibula of his left leg, Jan 17, 1935 Subsequently the leg became swollen and congested and "a clump formed under the knee space" Varicosities appeared in the leg and a clot formed in the left groin Hemrich died on February 25 from what his attending physician stated was thrombosis of the pulmonary artery, attributable to the fall, which injured the inside lining of the veins, where a clot of blood formed

The policy gave the insurer a right to an autopsy Accordingly, the agent of the insurance company, two days after Hemrich's death, informed the widow's attorney that an autopsy was desired and referred the attorney to a Dr Nixon of the Swedish Hospital for a consent form suitable for the widow to sign Dr Nixon furnished a consent form that would give, if executed, consent for the Swedish Hospital to make "such an autopsy and examination of the decedent's body as the hospital desired for a complete study of pathological changes in the internal organs, to complete the record of the case from a general scientific standpoint that in the future patients might benefit from the knowledge gained" The Swedish Hospital however, was in no way entitled to nor did it intend to procure any kind of an autopsy the autopsy was desired solely for the insurance company On being advised by her attorney that the proffered consent form seemed to contemplate an autopsy covering the whole body, unlimited as to time and intended for general clinical purposes, the widow refused to sign it Later in the day, about 4 30 p m the insurance company's agent served on the widow, in the absence of her attorney, a written request, asking her "To consent to performance of an autopsy on the body of the insured, now deceased" The funeral had already been set for the next day The widow again refused to consent The insurance company thereafter declined to pay any benefits under the policy The widow brought suit and recovered judgment in the trial court and the insurance company appealed to the Supreme Court of Washington

The insurance company questioned the sufficiency of the evidence adduced at the trial to indicate that death occurred under such circumstances as to charge it with liability under the policy The Supreme Court thought, however, that the testimony of the attending physician as to the cause of death was sufficient to take the case to the jury and to enable it to

pass on the matter The court thought also that an instruction was proper which told the jury that if it found that the accident set in motion some latent physical defect or started systemic disorders, and if Hemrich died as a result, it should find that within the meaning of the policy his death was caused by reason of the accident If the accident produced a change in or upon the body of the insured that caused his death, manifestly the accident was responsible for the death

The insurance company contended also that the refusal of the widow to consent to an autopsy relieved the company of liability The weight of the authorities, replied the Supreme Court, is that under a policy such as the one in this case the insurer is entitled to have an autopsy made provided it is seasonably made and reasonable as to time and scope The evidence the court concluded, was sufficient to warrant the submission to the jury of the question as to the reasonableness of the demand made by the insurer and as to the time and scope of the proposed autopsy The Supreme Court approved an instruction which told the jury that if the demand for an autopsy was not seasonably and reasonably made, it should find for the widow, since she was justified in refusing the demand, that in order for the demand to be reasonable and seasonable, the autopsy must have been reasonably necessary to determine the cause of death and must have been made within and under the terms of the policy and for the sole purpose of determining the cause of death, and that it was the duty of the insurance company to make a demand in accordance with the terms of the policy and in a manner and method in keeping with the proprieties of the occasion The insurance company objected to this instruction contending that the form of the demand was not an issue in the case This contention, replied the Supreme Court, is not tenable Two written demands were made One of them, on its face, was made by and on behalf of the Swedish Hospital, which was not interested in the matter, both demands contained language bearing on the question of the timeliness and scope of the requested autopsy which under the facts of the case, called for a finding by the jury as to the reasonableness of the demands The burden, concluded the Supreme Court is not on the beneficiary to initiate proceedings for an autopsy, nor to provide the language of the form to be used in making a demand for one, that is the duty of the insurance company if it desires an autopsy

The Supreme Court accordingly affirmed the judgment of the lower court in favor of the widow—*Hemrich v Aetna Life Ins Co (Wash)* 63 P (2d) 432

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Hydrogen Peroxide as Depressant of Gastric Acidity

—Culmer and his associates studied the effect of hydrogen peroxide on gastric secretion under controlled laboratory conditions and also in a few human subjects. Lavage of the stomach with hydrogen peroxide solution (from 0.5 to 3 per cent) produced a decrease in the acid of the gastric contents when either a meal or subcutaneous injection of histamine was used to stimulate acid secretion. This decrease was observed in the percentage of acid in the gastric contents and in the total milligrams of acid. The stronger the solution of hydrogen peroxide used the greater was the decrease of acid response. This decrease varied widely in different subjects and also from time to time in the same subject. However one of the dogs and two of the five human subjects consistently showed increases in acid secretion rather than decreases. The mucous secretion was always augmented. At times there was a complete absence of free acid (but no instances of complete absence of total acid) in response to histamine stimulus. However, it was the exception rather than the rule. While no chemical analyses for content of mucus were made it was obvious that generally an increase in mucoid or mucous secretion paralleled a decrease in acidity. This observation certainly was true in those tests in which no free acid was found. To obtain a significant reduction in acid secretion in peptic ulcer in response to histamine or a meal concentrations of from 1 to 2 per cent of peroxide must be employed. Even then stimulation as observed by Hurst with very weak solutions, may occasionally occur. A 3 per cent solution is too irritating. When the weaker solutions are used, the return of the secretory response to normal

is relatively rapid. In the case of a "susceptible" stomach, however, a 0.5 per cent solution applied every other day will reduce acid secretion significantly. However it might cause active ulcers to bleed for a patient with gastric ulcer showed bleeding with 1 and 2 per cent solutions and one of the dogs with a "normal" stomach showed marked bleeding after 3 per cent. Although it would be desirable to have some simple and innocuous method for reducing the secretion of acid by the stomach the authors do not feel that the use of hydrogen peroxide can be recommended without considerable reservation.

Changes in Children's Electrocardiograms—Drawe and her colleagues made electrocardiograms of 100 children with rheumatic heart disease and of fifty children with congenital heart defects and compared the averages for the different intervals with the electrocardiograms of 100 normal children. The principal abnormalities of the P wave in the electrocardiograms of children with rheumatic heart disease are definite and conspicuous notching widening and slight increase in height. The PR interval is definitely prolonged in a large percentage of cases of rheumatic heart disease. The abnormalities of the QRS complex are relatively slight. Only a slight tendency to right axis deviation was shown in the electrocardiograms of children with mitral stenosis and insufficiency. The children with aortic regurgitation showed a definite tendency to left axis deviation. The incidence of shifts of the RST segment is increased. Abnormalities of the T waves consisted of low T waves in all leads diphasic T waves in lead I and low, rounded notched and inverted T waves in lead II. The QT interval is often definitely prolonged in cases of rheumatic heart disease. Not all children with rheumatic heart disease have abnormal electrocardiograms. The main abnormalities of the P wave were in the group with the congenital defect in increase in the width and height and these were found chiefly in the electrocardiograms of children with pulmonary stenosis and tetralogy of Fallot and to a lesser degree in children with interventricular septal defects. The PR interval was slightly prolonged on the average. The average duration of the QRS in the electrocardiograms of children with congenital heart defect was longer than that in the electrocardiograms of normal children. This increase in duration was due mainly to the influence of the children with pulmonary stenosis. Notching and slurring of the QRS occurred frequently in the electrocardiograms of children with pulmonary stenosis, occasionally in those of children with interventricular septal defect and rarely in those of children with patent ductus arteriosus. All the electrocardiograms of children with pulmonary stenosis showed extreme conspicuous or definite right axis deviation ranging from 99 to 179 degrees. The T waves averaged considerably higher than those in the electrocardiograms of the

normal group. Abnormalities of the T waves are occasionally found, consisting of inversions of T and deep inversions of T_s. The QT interval was slightly prolonged in a few instances.

Results of Tonsillectomy and Adenoidectomy—To determine, if possible, what points in the history of the case and in the appearance of the throat are significant with reference to the clinical result obtained and to arrive at a more certain method of prognosis and more specific criteria for both prognosis and indications for tonsillectomy and adenoidectomy, Epstein observed 540 children between the ages of 2 and 13 years before and at intervals for two years after these surgical interventions. Histologic sections of the tonsils of 152 of these children were studied. Practically all these tonsils showed a greater or lesser degree of infection or connective tissue scars or both. Large tonsils were almost always infected. Tonsils that were cryptic usually contained more caseous material. Tonsils with much caseous material almost invariably had cryptic abscesses. Whether the tonsils were buried, cryptic, smooth, large or small bore no relation to the preoperative symptoms or to the degree of success of the operation. Excellent results were obtained with children of all ages in the relief of sore throat and of cervical adenitis, good results in the relief of mouth breathing, fairly good results in the relief of cough, and fair results in the relief of frequent head colds. Except in cases of tonsillitis or pharyngitis, the results for all complaints were only fair in children less than 6 years old. With the complaints of a cough and head colds the results were especially poor, particularly in children less than 4 years old. More consistently good results may be expected if the operation of tonsillectomy and adenoidectomy is postponed until the child is 6 years of age or older, especially if head colds or a cough is the complaint, except in the estimation of mechanical obstruction, the appearance of the tonsils in children is unimportant to the physician in arriving at a decision as to the advisability of the operation.

Relation Between Yaws and Syphilis—Turner studied the relation of yaws and syphilis to each other observing the clinical manifestations and the epidemiology of syphilis among a representative sample of an urban population in Baltimore and that of yaws among a representative sample of a rural population in Jamaica. The relation of both syphilis and yaws was observed among an urban population in Kingston. The disease phenomena produced in laboratory animals by organisms obtained from yaws and syphilis patients living in each of these communities were also studied. Easily recognizable differences were elicited between the two diseases. These differences cannot be explained on the basis of differences in factors such as race, the age of the person at the time of infection, the port of entry of the organism or the social and economic status of the affected individuals. Certain climatic factors seemed to play a part in determining the distribution of yaws but there was no clear evidence that these factors materially modified the course of either yaws or syphilis in the patient. Typical cases of each disease were found among persons living in the same environment in Kingston, Jamaica. The inoculation of rabbits with spirochetes from cases of each disease produced, in these animals, lesions which differed according to the disease from which the patient was suffering. Each of thirteen strains of yaws spirochetes studied gave rise to the same type of lesion in rabbits. Each of eight strains

of syphilis spirochetes recovered from persons living in Jamaica produced lesions which, while similar to each other, were readily distinguishable from those produced by yaws spirochetes. The ability to produce characteristic lesions in the rabbit was not lost on serial passage in this animal over a period of three years. It is concluded that *Spirochaeta pallida* possesses pathogenic properties which differ from those of *Treponema pertenue* and that the differences noted between yaws and syphilis in man are due, in part at least, to inherent differences in the causative agent of each disease.

Standardization of Anterior Pituitary Hormones—Colip contends that, irrespective of the number of physiologic effects that may be demonstrated for various anterior lobe preparations and irrespective of the apparent purity in a physiologic sense of this or that extract, the number of active principles in the normal gland in the living subject must of necessity be few (three or four). He does not believe that any one has as yet obtained an anterior lobe extract without some modification of the active principle or principles present in the living gland having taken place. He visualizes the naturally occurring anterior lobe hormone or hormones as rather large protein molecules to each of certain prosthetic groups of which some specific physiologic effect may be related. Such a view allows the hope that some day simpler compounds having specific physiologic effects may be obtained in crystal line form. These would not be true hormones but breakdown products resulting from controlled hydrolytic or other processes yet to be discovered. Meanwhile it becomes most essential that some system of biologic standardization of extracts should be agreed on, particularly so that experimental clinical studies can be satisfactorily made and the results of such adequately evaluated. As yet there is not enough information to allow absolutely rigid standards but an attempt can be made, and in the course of time methods of testing which are universally acceptable may be agreed on.

Vision Following Operations for Retinal Detachment—From the statistics of Dunnington and Macne compiled from patients operated on for retinal detachment at the Institute of Ophthalmology, New York Reese deduces that approximately normal vision (20/30) is obtained in only about one third of the successful cases and that the duration of the detachment is a factor in the visual result. From the microscopic exami-

nation in the routine cases of retinal detachment which come to enucleation, it is well known that cystic spaces frequently occur in the macular region and, to a lesser extent, elsewhere in the retina. This change is usually considered a very late sequel, and its occurrence has been noted almost invariably in eyes in which other pathologic changes were present, so that it is difficult to say to what extent detachment alone was responsible for the cysts. Twelve cases of simple serous detachment of the retina, ranging in duration from less than two weeks to four years, all showed cysts in the macula. It was here that they seemed to appear first and to attain their largest size. The cysts present in the retinas in the twelve cases seemed to be secondary to the detachment. No inflammatory element was present. There was a history of trauma in only three of the cases. Glaucoma was present in four of the cases. An operation for reattachment of the retina was performed in two cases but the changes incident to this did not seem to be a factor in the formation of the cysts. The edema of the retina and the cyst formations were probably due to the altered retinal circulation, which permitted a stasis of tissue fluids. This is more prone to appear in the macula first and more severely because this area is relatively avascular. When a detached retina becomes reattached, the gradual disappearance of the edema probably accounts for the slow progressive improvement in central vision and in the peripheral fields, which may take place over a period of months. If cyst formations in the macula have led to a destruction of the neurons, a permanent defect in central vision is to be expected. The presence of cysts in the macula or elsewhere in the retina cannot be recognized clinically as such by the ordinary ophthalmoscopic examination. When present, they may appear as poorly demarcated, grayish to yellowish white foci or as a rarefied area described usually as a "hole." In cases of detachment of the retina, the author finds that a cystic degeneration of the macula can be recognized if this area is sufficiently close to the underlying choroid to permit a reflection of a sharp narrowed beam of light from the choroidal surface. This beam of light, which is afforded by the usual ophthalmoscope, is directed to one side of the macular region to be studied and the observer shifts his head until the incident rays reflected from the choroid are detected in the nonilluminated field. This is comparable to retroillumination of the cornea by reflected light from the iris in slit lamp examination. In more advanced cases there may be an irregularly round rarefied area at the fovea surrounded by cystic spaces and apparently formed by their confluence. Such so-called holes can, of course, be seen by the ordinary ophthalmoscopic examination, but the cystic element around their periphery can be made out best by the method of retroillumination. In most instances, what was diagnosed clinically as a hole in the macula certainly represented conglomerate or confluent cysts.

*Origin and Growth of Renal Calculi A Randall Philadelphia—p 1009

Theory of Origin of Renal Calculi—Randall has tried to work back to what might be called a study of calculogenesis the stone's conception, its embryonic growth its fetal life cycle, up to the point at which size and symptoms made it a clinical entity. The first postulate made was that there must be an initiating lesion that precedes the formation of a renal calculus. A second postulate was necessary as to where such a lesion might be expected to be found. The renal papilla performs a complicated function is open to multiple physiologic variations and is known to suffer recognized insults that lead to pathologic changes, therefore it was postulated that the initiating lesion was to be looked for on the renal papilla. The general impressions obtained by a study of specimens are that there occurs a definite damage to the epithelial lining of the collecting tubules, and that the nearer one goes toward the tip of the papilla the more noticeable the changes are, that there is a marked damage to the ground substance of the interstitial connective tissue and of the basement membrane of many of the collecting tubules. Here and there the ground substance is broken up and granular and has a necrotic appearance. These changes appear to be followed by the deposition of calcium and calcium plaque formation. In places the calcium is deposited in damaged epithelium of the collecting tubules, but the primary deposit appears to be in the basement membranes leading to the formation of ringlike structures. No evidence of infection is seen in any of the sections presented. The most significant conclusion to be drawn is that the answer to the secret which has shrouded in mystery the true etiology of primary renal calculus is to be sought in an increasing knowledge of the physiology and pathology of the renal papilla.

Poisoning from Cutaneous Application of Iodine—The case that Seymour reports is the only one in the literature in which one of the severest types of cutaneous reaction was noted exfoliative dermatitis. Whether or not this reaction

was due to the iodine-tuberculosis (pneumothorax) relationship is an interesting question. Lass demonstrated that the intracutaneous administration of a solution of sodium iodide to normal subjects caused no reaction, whereas nine of fifteen patients with pulmonary tuberculosis so tested showed local reddening and wheal formation. His work and the case of exfoliative dermatitis presented seem to indicate that there may be factors other than that the iodides facilitate lysis of the tissue formed by inflammatory reaction which must be taken into consideration. The fact that the patient with exfoliative dermatitis did not show any reaction to iodine until six applications had been made suggests that sensitivity was being established which finally manifested itself in severe cutaneous and systemic disturbances. In five of the fourteen cases reported in the literature coryza was associated with iodism, thus making it conclusive that the reaction was due to iodine. These persons must have been extremely sensitive, as the total minimal dose of iodine in the form of potassium iodide required to produce symptoms of iodism is from 60 to 75 grains (4 to 5 Gm), and in these persons milligram quantities were used. Toxic manifestations were cutaneous and systemic. The mortality rate was 46.9 per cent. Death was attributed to the exfoliative dermatitis in the present case.

Serum Phosphatase in Jaundice—Since there still appears to be some difference of opinion regarding the clinical significance of an increase in the phosphatase content of the serum and its value in differentiating between hepatocellular and obstructive types of jaundice, and since this important question can be settled only by the accumulation of observations on large numbers of patients, Cantarow and Nelson carried out serum phosphatase determinations for thirty-one patients with obstructive and twenty-two with hepatocellular jaundice. There was a wide overlapping of phosphatase values in the two groups, which became even more pronounced when the present data were combined with those reported by other observers employing the same methods. It appears that this procedure is of no value in differentiating between these two types of jaundice.

Epidemic of Bacillary Dysentery—Gibbons discusses an outbreak of bacillary dysentery in a lumber camp in which there were 160 men, twenty-three women, twelve school children and four children of preschool age. From Oct 30, 1936, when the first case was recorded, until Nov 15, 1936, twenty-two cases had been reported to the first aid attendant. Enquiry revealed that the reported cases represented but a proportion of the total, for a number of men who had experienced a mild attack had not reported to the first aid station nor had any of the cases occurring in the women and children been reported, since these did not come under the care of the first aid attendant. Since less than half of the men were available for questioning on the day on which the camp was visited, no accurate attack rate can be recorded, but it is estimated that inclusion of all the unreported cases would show that about 35 per cent of the community had been infected. The clinical manifestations of the disease in this outbreak were acute diarrhea with abdominal cramps and tenesmus, fever, headache, anorexia and emesis in some cases. The severity of the symptoms varied widely in individual cases from mild diarrhea only to the acute symptoms. *Bacillus dysenteriae* Flexner and *Bacillus dysenteriae* Sonne were isolated from stool specimens of cases. The infection was food borne and was attributed to the contamination of food supplies by flies. The flies carried the infectious agent from an area, adjacent to the kitchen and food storage rooms, which had been polluted by sewage through a break in the sewerage system. This is the first outbreak involving *Bacillus dysenteriae* Sonne reported from British Columbia.

Immunity Against Diphtheria—The results of Schick tests and control tests that Straus carried out on forty-seven children after the single injection of concentrated alum precipitated toxoid in a dose of 0.5 cc show that three months after the injection two of the thirty-six persons tested gave positive reactions. At the retests, twelve months later, two of the previously negative subjects showed mild reactions, while two who had previously shown positive reactions were now negative. An additional eleven susceptible children immunized in another institution were all found to be Schick negative at the retest. Five of these were retested after eleven months and six after twenty-seven months. The superiority of these results over those reported previously suggests the importance of the method of preparation of the immunizing material. This question must be thoroughly investigated before a physician is advised to forego the great advantages of the single injection method.

Control of Rectal Bleeding in Ulcerative Colitis—For the control of rectal bleeding in ulcerative colitis patients Fradkin administered by rectum a mixture consisting of 20 per cent kaolin, 10 per cent liquid petrolatum and 70 per cent of a gel of aluminum hydroxide. Treatment with this mixture stopped the bleeding and decreased the number of bowel movements. Since the lesions are found in the distal half of the colon it was decided that 10 ounces (300 cc) of the mixture would be ample for one treatment. When a patient passed three or more stools in twenty-four hours, the medication was administered without a preliminary saline irrigation. Otherwise a small, low saline enema was given about two hours before the treatment. Six ounces (180 cc) of the mixture was diluted with 4 ounces (120 cc) of warm water. The treatments were carried out three times weekly, and then gradually reduced to once a week, as improvement was noted. The mixture was instilled slowly, taking fifteen to twenty minutes for the procedure. The blood streaks disappeared after the third or fourth week. In a few cases only four or six treatments were necessary. When blood streaking recurred, one or two weeks

of treatments readily controlled it. Twenty-six patients convalescing from acute attacks of ulcerative colitis were treated. The average number of treatments which were necessary to control the passage of blood streaked stools was 114. The average number of weeks required for treatments was 7.7. Sigmoidoscopic examinations were repeated as soon as the patients reported no visible blood in the stools. These observations in the majority of cases revealed clean, reddened, granular mucous membranes with only occasional superficial ulcerations which oozed slightly on manipulation. After further treatments, these lesions healed promptly leaving a pale, pink, granular mucosa.

Microflocculation Test for Syphilis—In view of the practical advantages possessed by the Hinton test, Davies modified it in such a way that 0.2 cc of serum could be used for a microtest and, in addition only 0.05 cc for a capillary test. Both tests employ the regular Hinton antigen emulsion, and the reaction which takes place is essentially the same as that in the Hinton flocculation test. By centrifugating the incubated mixture before reading the results advantage is taken of the fact that the "positive" floccules in the Hinton reaction rise to the top of the tube and tend to aggregate at the meniscus, where they are readily detected when present. Although similar in essential points, the microtest and the capillary test are described separately. In an evaluation series of tests on 300 blood specimens sent out under the auspices of the United States Public Health Service, each method demonstrated a sensitivity of 91.9 per cent and a specificity of 100 per cent. In a larger number of tests conducted in the routine of an infants' and children's hospital, the method has been found dependable and practicable. For emergencies, the tests appear to give accurate readings in one hour.

Vitamin E—In investigating the antisterility effect of vitamin E on fifty-eight rats, Martin found that a great difference exists between the amount of vitamin E required for antisterility effect and for growth and that the concentrate formerly considered to contain one vitamin actually contains at least two—one growth stimulating and one having an antisterility effect. The evidence presented favors the possibility of a multiplicity of factors. Two different preparations showed no growth effect and yet showed an antisterility potency in females of proved sterility. The preparation of crystalline α -tocopheryl allophanate from which pure vitamin E was regenerated by Evans and his co workers, should permit definite proof of this point when the preparation is available in sufficient amounts. Growth and antisterility may be due to slight alterations in a basic structure.

*Insulin Shock Therapy Critical Review R T Morse, Topeka—p 248
Acute Abdominal Disease C F Dixon Rochester Minn—p 253

Insulin Shock Therapy—Morse reviews some publications dealing with insulin shock therapy in schizophrenia. Sakel, according to Glueck adheres strictly to a biochemical hypothesis, which he sums up accordingly: 1 The insulin puts a barrier between the cell and external stimuli thus putting the cell at rest and enabling it to recuperate. He assumes that by keeping the pathologically conditioned cell pathways in abeyance the original, normally conditioned pathways have a chance to reestablish themselves. 2 The profound, almost annihilating assault which the cell experiences during the insulin shock perhaps actually eliminates the recently established pathologic pathways and in the course of recovery from shock, only the older, well established prepsychotic pathways become reanimated. 3 A general detoxication of the entire organism occurs through the effect of the insulin on the entire metabolic status. Glueck believes that 'although the therapeutic approach is essentially of a biochemical nature, its effects so far as they lead to a modification of psychopathologic states can in no way be looked on as identical with those characteristics of a strictly causal therapy, such, for instance, as the psychoanalytic therapy of a hysterical phobia. On the contrary, one gains the impression of a radical and fairly rapid generalized disturbance of the vegetative, neurologic and psychic integration of the patient, which calls forth in its turn a rapid reintegration immediately on the neutralization of the hypoglycemia. But in addition to the important role which the sugar metabolism plays in this catabolic and anabolic process psychic factors seem also to be of considerable importance.' He is of the opinion that the repeated insulin shocks may serve to clear the atmosphere, so to speak, of the neurotic and psychotic state, especially in view of the fact that these experiences of acting out are followed by an amnesia and thus escape ego and superego criticism with its subsequent guilt and shame. Glueck divides recovered patients into two groups: one with a distinct emphasis on the virtues of repression and an attitude that the past was best buried and the other with a definite preference for the so called working through and reintegration. If such is the case, a study of the tendency to relapse in these two groups should be of great interest.

Hypertension Caused by Food Allergy—Liston is convinced that certain foods ingested by individuals sensitive to them will cause overstimulation of the vasoconstrictor nerves of the arterioles, thus raising the blood pressure as long as any of the food remains in the system. Furthermore, he feels justified in stating that most of the vasoconstrictor action is on the arterioles, for he has repeatedly seen blood pressure of a duration of years fall to normal within four days after removal of the offending food, and thus in persons whose arteries were sclerosed and tortuous. He has one patient sensitive to pork who cannot eat eggs fried in lard without a rise in blood pressure. Another patient was sensitive to wheat, and ingestion of any wheat caused a marked swelling of the tongue with an increase of 60 mm of mercury in blood pressure. He has worked out the cause of the hypertension in about fifteen such patients. In all cases he uses either the elimination diet or skin tests of the foods for hypersensitivity.

Perforation of Nasal Septum in Copperplating—

In March 1936 Barsky saw two employees of a copperplating establishment reporting for treatment of infected abrasions and acute coryza. They volunteered the statement that many of their co-workers suffered from similar complaints. Examination revealed the presence of shallow ulcerations of the nasal septum and turbinates. As a result of these observations, all employees of the plating department of this establishment were examined and a hygienic study of the premises was conducted. The disturbance was effectively corrected. There were no recurrences of the difficulties in the old workers, nor did any

appear in new employees. The direct causes of the disturbance were improper control of baths, failure to exhaust the spray thus produced and inadequate general ventilation.

- *Report of Two Outbreaks of Food Poisoning J C Geiger — p 765
- Incidence of Spontaneous Tumors in Colony of Strain C₃H Mice H B Andervont and W J McEleney — p 772

Food Poisoning—Geiger discusses the 110 reported cases in twenty-eight families that were affected in an outbreak of food poisoning traced to cream custard cakes from a bakery. Ample opportunity for contamination of the custard during its preparation, storage and handling were manifest on direct observation of procedures followed. Laboratory confirmation of the epidemiologic investigation included high bacteria colony counts per gram of custard—*Bacillus coli* and hemolytic and non hemolytic strains of *Staphylococcus aureus* (heavy pigment producers), toxin formation by hemolytic *Staphylococcus aureus* on mediums rich in starch (produced marked vomiting and diarrhea in kittens on intraperitoneal injection). Control studies made on similar cakes several days later showed lower counts even on the third day, with *Bacillus coli* and non hemolytic strains of *Staphylococcus albus* and *aureus* present. The second outbreak is that of botulism apparently due to European commercially canned antipasto. Of a group of sixteen persons eating dinner together, ten were hospitalized for the treatment of a condition presenting the clinical picture of botulism. Of the ten hospitalized persons, one was found not to present evidence of the intoxication, three died and six recovered. An additional person, who was not hospitalized gave a history of certain symptoms and signs indicative of intoxication. The antipasto served at the dinner was a mixture of the contents of two cans, both imported. At the time of hospitalization, one of the patients said he had opened the can and was impressed by the "slushy" contents, which "squirted." This patient stated that the antipasto "did not taste right." Other members of the affected group commented on the "bitter taste" of the mixture. A 13 year old girl, liking the tuna fish especially, ate two pieces of it. She was the most seriously ill of the group and the first to die. The two cans involved were never recovered, so that positive and final proof of the source of the intoxication was not obtained. One of the brands had not been regularly distributed in California for about nine years and the stock in the involved grocery store had been on the shelves for approximately five years. That botulism was the cause of death was proved in two of the fatal cases when the toxin of *Clostridium botulinum*, type A, was demonstrated in the laboratory. The toxin was not demonstrated in the third fatal case.

Spontaneous Subarachnoid Hemorrhage—McDonald and Korb report seven cases of spontaneous subarachnoid hemorrhage in order to call attention to the frequency of the disease.

and its occurrence in patients without arteriosclerosis with hypertension, or neoplastic or anemic disease which bleeds. Four of the patients died and three recovered. None of them were known to be sick before the apoplexy. All of them showed symptoms and signs which led to recognition of the disease during life. The disease is not an uncommon condition and can be readily recognized by the syndrome of sudden severe headache, stiffness of the neck, double Kernig's sign, a bit of fever and a bloody spinal fluid.

Tetanus Immunization with Alum-Precipitated Toxoid—McBryde has used alum precipitated toxoid made from tetanus toxin of a minimal toxicity of 15,000 minimal lethal doses per cubic centimeter which was detoxified by adding 0.3 per cent formaldehyde and incubating at 39 C until a dose of 10 cc of the material caused no tetanic symptoms when injected into guinea-pigs weighing 350 Gm. Equal parts of a 4 per cent solution of aluminum potassium sulfate were added to the plain toxoid and it was treated according to the method described by Wells, Gordon and Havens for diphtheria toxoid, 1 cc of this material when injected into the guinea-pigs resulted, in forty days in an average production of 6 units of antitoxin per cubic centimeter of blood serum. This was at least ten times the immunizing value of the original toxoid from which it was made. A group of ninety-four Negro children received subcutaneous injections of 1 cc of this toxoid. Forty-five days later serums were collected for antitoxin titration, and seventy three days after the first injection a second injection of 1 cc of toxoid was given. Serum was again secured fifty-four days after the second injection or 127 days after the initial injection. No severe reactions were encountered in the 180 injections given. Forty-five days after the first injection only two children had less than 0.01 unit of antitoxin per cubic centimeter. The great majority had from 0.01 to 0.1 unit per cubic centimeter. Thirteen children had more than 0.1 unit and two had 0.25 unit per cubic centimeter. When tested fifty four days after the second injection or 127 days after the primary dose, there were marked increases in the antitoxin content. Of the eighty-five children tested, no child had less than 0.1 unit per cubic centimeter, while five had values from 0.1 to 0.25 unit, eighteen had from 0.25 to 0.5 unit, twenty-six had from 0.5 to 1 unit and thirty-one had from 1 to 2 units per cubic centimeter. Three children had 2 units and two had between 3 and 5 units per cubic centimeter. Tetanus toxoid is of special value in children who are allergic. Many practitioners will wish to immunize in a routine manner the children under their care. Though the prevalence of tetanus is low, some children acquire the infection from wounds which are so trivial that no antitoxin would have seemed advisable

at the time of injury. Present knowledge would indicate two injections of alum-precipitated tetanus toxoid at an interval of two months followed by a third injection at the time of injury. This will raise the serum antitoxin to the level reached by injection of 1,500 units of antitoxin.

Pulmonary Changes in Malta Fever—Lafferty and Phillips are convinced that pulmonary changes occur in many persons who have undulant fever, and they are led to believe that there are pathologic processes in the lungs of some of these patients which, in all probability, are a direct result of the infection. Although x-ray observations in these cases do not exactly coincide with those of other observers the disease often seems to manifest itself in the lungs by peribronchial congestion or, rather, diffuse bronchopneumonic process and rapidly progressing fibrosis. The authors have not had any experience with patients who have had extensive pneumonic processes, either lobar or lobular.

Simple Procedure in Fractures of Spine—Any one who has seen patients with spinal fractures immediately placed in plaster has encountered in some of them an uncontrollable train of abdominal symptoms and has seen some become so distended as to require removal of the plaster or require opiates in large quantities. While handling one such patient, a nurse who had previously required considerable abdominal surgery, Binkley sought a temporary measure that might do no harm until these abdominal symptoms could subside. She was accordingly placed on an ordinary Simmons bed which had the usual back rest and knee support controlled by cranks, her head being placed at the foot of the bed with the site of fracture just over the apex of the elevation. The degree of hyperextension could readily be controlled by turning the crank at the foot of the bed. This accomplished the results so satisfactorily that she was never changed until roentgenograms showed that she was ready for a brace. Both anteroposterior and lateral roentgenograms were taken without removing the patient from the bed, and the method proved so satisfactory that it has since been employed with equal success in four other cases.

Enuresis in Children—McGregor discusses seventy cases of enuresis in children treated for the most part by securing the patient's interest in his own complaint. The enuresis had in each instance been present since birth, but cases of enuresis in mentally deficient children have not been included. A physical examination was made to exclude organic disease. In the absence of this the child was presented with a small calendar, to be kept by the bedside, on which the date of each dry night was to be recorded by the patient himself. Beyond spending the necessary time to interest the child in these measures and seeing the patient at regular intervals afterward, no treatment was used and no medicines were prescribed. The treatment is best carried out at a clinic, where the atmosphere of competition and enthusiasm that prevails in the waiting room is an adjuvant to success. At least 60 per cent of cures maintained over a length of time were obtained. Whatever may be the psychologic significance of enuresis, and however important the coexistent physical defects in initiating or maintaining it, it seems reasonable to regard the failure to outgrow the habit at the normal age as a neural motor reaction in response to many different environmental situations and bodily states, whether emotional, physical or a mixture of the two, and to assume that in no two cases is it due to an identical combination of factors. At all events it is quite possible to persuade most of the children to change the habit by simple encouragement or by other suggestive means, nor is the task laborious.

Left Inframammary Pain—Smith and his associates describe the syndrome frequently known as left inframammary pain. The salient points discussed are (1) the existence of a group of symptoms of which left inframammary pain was the chief, (2) the obvious role of physical or mental fatigue in producing or aggravating the syndrome, (3) a condition in which the blood sugar generally tended to fall to abnormally low fasting levels and in which a state of increased sugar tolerance was found, and (4) the prevalence among these patients of particular types of electrocardiogram. An account is given of an investigation into the clinical features and metabolism of twenty-six patients suffering from the left inframammary pain syndrome, but from no recognized organic disease in any

system. About half of the experimental group showed abnormally low fasting blood sugar, even though the figure of 70 mg per hundred cubic centimeters was taken as the lower limit of the normal. Sugar tolerance curves often showed an increased tolerance, the curves reaching an early, and frequently low peak. On the other hand, in two patients an unsuspected diabetes was brought to light, and in three others hyperglycemia without glycosuria. The electrocardiogram in the subject having left inframammary pain is found frequently to show certain features heretofore regarded as normal. The following changes would ordinarily be grouped among normal tracings but occurred with such frequency among these patients that they have received special attention: 1. T_1 not greater than P_1 in amplitude. 2. T_2 not greater than P in amplitude. Diphasic T or T_3 with or without 1 or 2, or 1 and 2. One or more of these conditions were fulfilled in sixteen patients. It is suggested that this pain is the cardiac expression of a metabolic derangement that affects the body as a whole and that the disturbance is related to an underlying endocrine imbalance.

Use of Insulin in Nondiabetic Malnutrition—Fillman emphasizes that insulin is not to be regarded as a cure for pulmonary tuberculosis. Its indiscriminate use is fraught with danger and, as with so many other valuable therapeutic measures (e.g., artificial pneumothorax), inevitably brings it into disrepute. There are some who claim that insulin can be used in all cases of pulmonary tuberculosis. His own experience has failed to show any appreciable results in advanced active disease, although good results have been claimed in such cases. A patient whose appetite is poor, who fails to put on weight, who is afebrile, whose disease shows no gross evidence of activity and with whom the usual medicinal measures have failed to correct these symptoms is eminently suitable for insulin therapy. The author has avoided using insulin when there is fever, active pulmonary disease, hemoptysis or marked hypotension or when severe reactions follow the injections. It has been his practice to begin the course of treatment with a hypodermic injection of 5 units of insulin. This is given twenty minutes before the principal meal and is followed three hours later by a glass of milk or a tablespoonful of dextrose to avoid any risk of hypoglycemia. The injection of 5 units is continued daily for the first week. This dose is increased by 5 units weekly, so that in the sixth week 30 units daily is given (15 before lunch and 15 before dinner). The course of insulin treatment is from two to three months. It can be repeated at intervals and the author has sometimes given two or three courses, although in many cases the effects of insulin have been maintained after the first course has been discontinued.

*Pigmented Basal Cell Epitheliomas (Contribution to Pathologic Anatomic Research) J Gate G Massia and J Delbos—p 337
Exotic Epidermophyte Case J Payenneville and E Rivaier—p 378

Pigmented Basal-Cell Epithelioma—Gate and his associates describe a variety of basal-cell epitheliomas with a histologic picture characterized by an abnormal quantity of pigment granules. There are a number of other neoplasms belonging to this group which to a smaller degree likewise contain pigment granules. But the variety described is differentiated by its abnormally large admixture of pigment bodies within the neoplasm. In the initial stage the small cell shows a well defined chromatic nucleus and very fine pigmented granules at the outer zone of the cytoplasm. In the next stage the nucleus begins to be less visible, the pigment granules become larger in size and quantity until they finally occupy the whole cell. In the third adult stage the cell is just a bag of pigment granules and has no nucleus whatever. In the final stage of senescence the cell walls are being destroyed and the pigment granules are spilled. These basal cells are encountered at the periphery of cancerous growths and are more abundant in their center. This pigmented cell is of epithelial origin, in the basal layer of which there are dendritic cells suspected of producing melanin (melanoblasts) and distributing it along their branches. It seems that there is a sort of symbiosis between these so called Langerhans cells and the cancerous cells. When the basal layer is encroached on by the neoplasm it provokes a hyperformation of pigment, which subsequently migrates toward the irritating lesion. Those melanomas are rare and it is extremely difficult to establish their etiologic factors. Its histologic peculiarity imparts its brown gray or dark appearance and with the help of the dopa reaction melanoblasts may be differentiated from melanophores. However the morphologic aspect of those elements always remains different from that of cancerous cells. The neoplastic tissue is often intimately permeated by connective tissue fibers and along those fibers it is possible for the pigment cells to become settled even as far as the center of the tumor. Any intervention for bioptic specimens may stimulate the neoplastic process. It is therefore prudent to suspect every pigmented neoplasm of being malignant and to make a biopsy only after physical therapy has been instituted. For the same reason any surgical intervention is regarded as dangerous. The authors are in favor of roentgen therapy, for which purpose they use from 3,500 to 4,000 roentgens without filter, a spark gap of 18 cm, 4 milliamperes current and a focus skin distance of 22 cm. To secure a thorough irradiation it is well to use fields extending from 2 to 5 mm beyond the borderlines of the neoplasm. After about a week the tumor begins to ulcerate. At this stage no curet or scissors may be used. It is enough to use warm physiologic solution of sodium chloride applied with a syringe. The wound is then covered with an ointment of bismuth subnitrate and zinc oxide and dressed. Some authors prefer diathermocoagulation, perhaps because of its greater cosmetic value. But it is a painful procedure and it must be preceded by a locoregional or local anesthesia. Care must be taken to inject any healthy tissue with the anesthetic. The first treatment consists in forming a barrier by a series of small coagulations against dissemination. The second treatment consists of coagulating layer after layer, the layers being shaved off until healthy tissue is reached. The dressing may be dry or slightly greased. Cicatrization takes about three weeks.

*Hypersensitivity to Insulin J L Masek and C Khr—p 301

Relation Between the Pathogenic Power and the Evolution Cycle of Some Germs and of the Streptococci in Particular R Natuelle—p 334

Hypersensitivity to Insulin—Masek and Khr have noticed that the hypoglycemia which follows the injection of insulin differs considerably in diabetic from nondiabetic patients notably those with cirrhosis, obesity, cachexia, pernicious anemia or certain neuroses. After reviewing the various hypotheses regarding the physiologic reaction to insulin treatment the

authors accept the view that insulin is fixating dextrose in the tissues in unstable combinations. This takes place in the intramuscular and subcutaneous spaces outside the blood stream in a form analogous to protein sugar. During all their investigations the authors were mindful of the dextrose regulatory influence of other glands with internal secretion and their direct action on insulin. This resistance to insulin may have a humoral aspect but it may also assume contraregulatory qualities (adrenals and hypophysis) seen mostly in diabetic patients in whom the islands of Langerhans are not affected. In those rare cases it is assumed that the increase in the proportion of peptic ferments inactivates the insulin. In their effort to determine the capillary glycemia in fasting patients they gave equal injections of insulin to patients with a high percentage of glycemia with acetoneuria and to some with less than 180 mg per hundred cubic centimeters of glycemia and no acetoneuria. In this manner they found that patients with grave diabetes are slower in recuperating to former levels of their carbohydrate metabolism. Having obtained similar data in patients with hyperthyroidism, they consider the strong diminution of the glycemic index as the expression of a functional disturbance in the contraregulatory apparatus. At the same time they arrived at the hypothesis that nutritional factors (diet deficient in carbohydrates) as well as secondary factors (phlorhizin or endocrine disturbances) which tend to diminish the carbohydrate reserves have a pronounced influence on the abnormal development of the blood sugar. In animals in which they brought about an artificial carbohydrate deficiency they made the observation that the hypoglycemic phase was greater and of longer duration when insulin was followed by an injection of epinephrine. The authors deem it necessary for the sake of solving the problem to give greater attention to internal chemical conditions. This would mainly concern the possible relations between the phenomena discussed and those of the so called protein sugars.

Cause of Death in Experimental Choleperitoneum D Divella—p 249

Donaggio Reaction After Operations—Perazzo followed the behavior of Donaggio's obstruction phenomenon of the urine in relation to the amount of platelets in the blood and the velocity of sedimentation after operation. His observations were made in a group of twenty patients suffering from chronic or acute surgical disease tumors and cancer. Surgical trauma induces rapid but transient appearance of the obstruction phenomenon of the urine which follows the clinical evolution of the postoperative period. The intensity of the phenomenon depends on the seriousness of the operation performed. There is thrombopenia. The velocity of sedimentation parallels the curve followed by the obstruction phenomenon. The reaction of the obstruction phenomenon however is rapid and transient whereas the velocity of sedimentation increases late and slowly decreases to normal figures. According to the author the obstruction phenomenon is due to elimination of blood colloids through the urine. The colloids originate in a process of cellular disintegration from surgical trauma. Thrombopenia is due to the antitoxic functions of the platelets on the colloids in the blood.

Modifications of Lung Parenchyma After Sympathectomy—Biasini made an x-ray and anatomic study of the modifications of the lung parenchyma in experimental cervical sympathectomy. He states that the modifications depend on the degree of sympathectomy and the side on which it is done. Unilateral sympathectomy induces reduction of the bronchioles and small blood vessels which is more accentuated in the lung of the side on which the operation was done. The modifications of the vessels and bronchioles are more accentuated after bilateral sympathectomy. They are more intense at the upper field of the right lung. The modifications induced by unilateral or bilateral sympathectomy are more accentuated a long time after the operation. They are due to permanent changes in

the circulation of the lung due to disturbances of the sympathetic innervation of the organ. The modifications of the heart originate partially in local disorders of sympathetic innervation. Cervical sympathectomy induces elevation of the diaphragm, especially of the right side, probably through anatomic phrenic and cervicosympathetic connections. The author says that the results of the experiments show the dangers of cervical sympathectomy in the clinical field and the advisability of not resorting to the treatment.

Technic for Aspiration Biopsy—According to Aghaloro, uterine curettage is the classic method for diagnosis of intra-uterine infections and tumors. Next in importance is biopsy by aspiration of fragments of the uterine mucosa, which is indicated when intra-uterine curettage is contraindicated. The author's technic for a biopsy is as follows. The fragments of the uterine mucosa are placed in a glass tube containing sodium salt solution, are separated and then are fixed in acetone for a few minutes. The fragments are then frozen and sectioned. The sections are stained with a mixture consisting of three parts of a 1 per cent aqueous solution of eosin, seven parts of acetone, five parts of methylene blue aqueous solution and five parts of alcohol at 95 degrees. The slides are placed in the staining solution and the latter warmed until the acetone odor is entirely gone. Then the slides are left undisturbed in the solution for five or ten minutes more to take an even stain. The latter is then wiped off the slides with drying paper. The sections are mounted with Canada balsam or syrup of acacia. Sections thus obtained are very clear. A diagnosis can be made promptly because of the fact that the entire process requires little time.

Pregnancy and Pulmonary Tuberculosis—Infantozzi states that the transplacental origin of tuberculosis has been proved. The filtrable tubercle virus may pass through the placenta and contaminate the fetus, which is born apparently normal and later on develops tuberculosis. Pregnancy, labor and the puerperium, especially if they take place repeatedly, stimulate development of latent tuberculosis and aggravate the condition if it is present before pregnancy. Pulmonary tuberculosis often induces abortion or premature delivery. The infants may be born normal or apparently so. In the latter case they are under weight, are congenitally weak and may die in early infancy. It is advisable not to allow marriage, pregnancy and lactation to women suffering from pulmonary tuberculosis. If pregnancy takes place, however, expectant treatment, with the patient under medical supervision, is indicated in fibrous or healed tuberculosis and if the disease has been controlled for more than three years, especially in patients who are in favorable economic and social condition. If tuberculosis is in evolution, it is advisable to stop pregnancy if the patient reports for examination before the third month. Otherwise pregnancy may continue with the patient under medical supervision. Pregnancy aggravates tuberculosis in evolution and the severe forms, especially laryngeal and active ulcerocaseous tuberculosis. Congestive and pleural forms also are aggravated, but not so intensely as the severe forms. Women suffering from apyretic chronic tuberculosis with cavitation can stand preg-

nancy fairly well. Infants of tuberculous mothers have to be given the Calmette vaccine and be placed away from the mother in a home of healthy people, preferably living in the country. The infants have to be nursed by healthy women and never by the mother.

Roentgen Sign of Acute Psoriasis—The sign described by Varela Fuentes and Iraola consists of the deformation of the roentgen shadow of the psoas muscle, which is wider than that of the normal muscle on the other side and shows a convex outline from the first lumbar vertebra to the iliac crest, instead of the straight border shown by the shadow of the normal side. The deformation appears early in the development of psoriasis, at a time when flexion of the thigh and the signs previously described are not as yet in evidence. The sign is of value in the early diagnosis of acute psoriasis, especially if it is located high and in the differential diagnosis of the condition from acute appendicitis, as it shows inflammation of the muscle. In the author's case the operation confirmed the diagnosis. An abscess was found at the upper part of the muscle, deeply seated against the vertebrae. Roentgenograms taken one month after the operation showed correction of the deformed roentgen shadow.

Atheroma of Aorta—Saccon and Zimman's patient, aged 71, was apparently in good health when he developed an intense pain in the left leg, fever and chills. On examination, he was found to be suffering from senile arteriosclerosis. An intermittent claudication of the leg had developed a short time before. The second aortic sound was accentuated and it was of a clangorous character. A clinical diagnosis of ulcerated, aortic embologenic aortic atheroma was made. There was no time to take a cardio-aortic teleroentgenogram because of embolism of the sylvian artery. The necropsy showed the presence of generalized atheroma all through the entire arterial tree. The arteries were the seat of a process in which old and new areas of atheroma, freshly formed ulcers and scars of old healed ulcers occurred in alternation. According to the author, generalized sclerotic atheroma may follow a chronic evolution for some indefinite time. During this time focal transitory atheromatous infection may be produced, with fever and slight arterial obstruction, which is spontaneously cured or without arterial obstruction at all. Embologenic infected ulcerated atheroma is fatal. Its development and the mechanism of production of the consequent septicemia parallel those of venous septicemia and malignant endocarditis. In venous septicemia the intravenous septic foci induce a migrating thrombophlebitis and repeated embolism to the lungs. In malignant endocarditis the septic intracardiac foci cause cardiac disturbances and embolism to the arterial system. In ulcerated, infected atheroma the intra-arterial septic foci cause atheromatous septicemia and a bombardment of embolisms in the splanchnic and peripheral arteries.

Vitamin C Deficit During Pregnancy—Gaetgens and Werner investigated by means of the serial tolerance test of

Jezer and Kapp whether healthy pregnant and lactating women

have a vitamin C deficiency. They found that 62 per cent of the women who were pregnant for the first time had a vitamin C deficit and that 70 per cent of those who had been pregnant before had a vitamin C deficit. Tests made during the period of lactation do not permit the conclusion that lactation as such increases the vitamin C requirements. A vitamin C deficit, which existed during pregnancy, was not further increased by the process of lactation.

Disinfecting Substances for Determination of Blood Alcohol—Gutschmidt directs attention to the fact that the substances which are used for disinfecting the ear lobe or the finger tip previous to withdrawing a blood specimen for the determination of the alcohol content should not contain volatile or oxidizable substances such as alcohol, because the use of such substances may lead to errors in the determination of the alcohol content of the blood. He describes studies on various disinfectants, which led him to differentiate three groups. To the first group belong those which evaporate on the skin and which, if sufficient time is allowed to elapse before withdrawal of blood, will not change the blood alcohol values. However, these are not suitable for practical use, because it is usually impossible to await complete evaporation. This group includes alcohol, ether, benzine and so on. To the second group belong substances that do not evaporate on the skin but rather in Widmark's test tube, where they may effect reduction. To the third group belong substances that do not influence the titration values. The author concludes that only the latter group, which includes mercury bichloride and mercuric cyanide, is suited for the disinfection of the skin, when the alcohol content of the blood is to be determined.

Mortality of Premature Births—Siedentopf reports the results of studies on the survival value and mortality of 1,012 premature births. These premature infants were born at the Leipzig clinic from 1920 to 1923. During 1934 and 1935, that is, from ten to fourteen years after birth, 188 of the original number could be ascertained to be alive and 100 of them could be subjected to an examination while information could be obtained about the other eighty-eight. It was found that, among those prematurely born who survive beyond the age of 10, physical or mental defects are not greater than among other children. Thus it can be said that prematurely born infants who complete the first decade of life have the same prospects as children who were not born prematurely. In discussing the mortality of premature births the author states that there were 305 stillbirths, 152 patients died at the clinic, 110 died before the end of the first three months, forty-two died before the completion of the first year and twenty-seven died later. Of those who weighed less than 1,000 Gm at birth, none left the clinic alive. The author thinks that the children who die at the clinic, that is, under the best possible care, are not viable but that among the others, who died later, there were many who, under suitable care, might have survived.

Acute Myeloblastic Leukemia After Malaria Therapy—Adelheim reports the clinical history of a woman, aged 55, who was subjected to malaria therapy on account of dementia paralytica. An acute leukemia developed and the patient died. To be sure, it is not known whether the leukemia existed before the vaccination malaria, but if so, the exacerbation at least must be ascribed to the influence of malaria. However, in view of the fact that the woman's general condition was favorable before the malaria therapy was begun, it is not probable that the leukemia existed before. The slight splenic tumor that existed previously but increased enormously during the malaria attacks may have been of syphilitic origin. The author believes that the malaria therapy caused the acute leukemia. He advises

blood tests in the course of malaria therapy and thinks that hematologic studies on a large number of patients undergoing this treatment will reveal interesting data on the condition of the blood during malaria.

*Depth Dose in Epilation: Irradiations of Head A. Proppe —p 139

*Roentgen Lesions Following Therapeutic Irradiation J. Korbler —p 146

Depth Dose in Epilation of Head—Proppe says that the most important problem in the roentgen epilation of the head is the possibility of an impairment of the brain. He made experimental studies in order to obtain more information about this problem. Being convinced that the depth doses determined on water and paraffin phantoms cannot be applied to the human cranium, he made experiments on a skull from an adult. He found that, when epilation is done by means of 300 or 400 roentgens, approximately 105 or 140 roentgens reaches the cerebral cortex. He thinks that such a dose is probably harmless as far as adults are concerned but that in children it should be considered that the brain cells might have a greater sensitivity to rays and that the dose reaching the brain is higher because the cranium is thinner and poorer in calcium. Investigations on the possibility of injury to the cerebral cortex at the sites of overlapping of the ray action led him to conclude that in the region of the cerebral cortex the overlapping of the fields of irradiation does not result in the dangerous increases in dosage that are occasionally observed on the scalp. This explains why in severe roentgen injuries of the scalp there are no lesions in corresponding localizations on the cerebral cortex. However, since in case of irradiation from several sides it is the region of the basal ganglions, of the thalamus and of the hypophysis which is in the cross-fire of the rays, the author made experimental studies on the dose that reaches this region. He determined that, if the rays are applied from four different directions, 70 per cent of the surface dose will reach this region; if applied from five directions, from 80 to 85 per cent, and, if applied from six directions, from 110 to 120 per cent. In children the depth doses are even larger. The author advises that in the after-examinations of patients who have undergone roentgen epilation, not only a possible impairment of the intelligence should be searched for but also changes in the functions that are controlled by the basal ganglions. Moreover, he thinks that Schreus's irradiation from four sides is the method of choice for roentgen epilation. He advises against irradiation from five or six directions.

Roentgen Lesions Following Therapeutic Irradiation—Korbler says that, in spite of the fact that many roentgenologists assert that they have never seen roentgen burns, it must nevertheless be admitted that such burns do occur. To be sure, they are often not seen by the one who has caused them, but by others, for they often appear years later. The author cites a case from the literature in which a roentgen lesion recurred thirty-three years after the surgical cure of the first roentgen lesion and thirty-six years after the irradiation. He then describes several cases of late roentgen lesions which he himself observed. Among the patients with late roentgen lesions there is a surprisingly large number of physicians. He ascribes this to the fact that physicians more readily observe the changes that at first are rather inconspicuous. Moreover, physicians mention the earlier roentgen therapy in the anamnesis whereas lay persons either ignore the slight changes or fail to mention the earlier roentgen treatment, when they request medical aid. Another explanation might be that in physicians more often than in lay persons other eliciting causes such as subsequent irritations, are added, for there are usually other

factors besides the roentgen irradiation which cause the late sequels. The author further discusses regional differences in the sensitivity of the skin to roentgen rays, pointing out that the skin of the palmar surface of the hands and that of the neck is especially sensitive to roentgen rays. Regarding the prevention of roentgen lesions, he says that great caution is necessary in cutaneous irradiations and that the irradiated skin must be carefully guarded against all irritations, be they of a mechanical, chemical or thermic nature. Even exposure to the rays of the sun is dangerous. The author also stresses the necessity of keeping exact records of every irradiation, particularly of the dosage.

*Denervation of Renal Pedicle in Essential Hypertension W Lowenstein and A Weissmann—p 675

Denervation of Renal Pedicle in Essential Hypertension—Lowenstein and Weissmann point out that, whereas today blood pressure disease is regarded by the majority of clinicians as a functional disturbance of central origin, formerly it was considered generally the result of renal disease. Lately, however, the kidneys have been placed again in the center of the pathogenesis of hypertension. The experiments carried out by Braun and Samet were chiefly responsible for the renewed emphasis on the role of the kidneys in the pathogenesis of hypertension. Following a review of these studies and of the objections raised against it, Lowenstein and Weissmann report the clinical history of a woman with severe hypertension and retinitis. Since various therapeutic measures effected no improvement, it was decided to resort to denervation of the renal pedicle. The right kidney was decapsulated and the renal artery was exposed for a distance of 6 cm. The adventitia was removed and a cresol-phenol preparation was applied to the artery. This application resulted in necrosis of the tissues. Immediately after the operation, the blood pressure decreased considerably but the other symptoms were not changed. Moreover, the decrease in blood pressure was only temporary, for it soon increased again to the old level. The authors suggest that the decrease in blood pressure was not caused by the denervation but rather by the fever that followed the operation, for they repeatedly observed that intercurrent fever reduces a high blood pressure. They agree with F Fuchs, who rejected the theoretical conclusions which Braun and Samet deduced from their animal experiments on renal denervation.

Experimental Data Bearing on Treatment of Acute Generalized Peritonitis K F Kaplan—p 65

Treatment of Pneumococcal Peritonitis—On the basis of his own material and of a review of the literature, Koch concludes that pneumococcal peritonitis is a disease of children of the preschool age and almost exclusively of girls. The sources of infection are the bowel, the appendix, the pleura and, in girls, the genitalia. Hematogenous infection following sore throat is possible. The symptom complex considered typical for this condition is rarely observed in practice, there being, as a rule, no pathognomonic signs of the disease. Differentiation from acute appendicitis presents great difficulties. Among suggestive symptoms the author mentions sudden onset frequently preceded by diarrheal stools, herpes labialis, high temperature, rapid pulse, prostration and a sharp neutrophilic leukocytosis. The finding of pneumococci in the vaginal smear is suggestive but not decisive. The finding of the pneumococcus in the blood favors definitely pneumococcal peritonitis. The history of a preceding angina vulvovaginitis, bronchitis or pneu-

monia is suggestive. Palpation gives most valuable information. In acute appendicitis there is much rigidity, while in pneumococcal peritonitis the abdomen presents a soft doughy enlargement with marked distention and diffuse tenderness. The author does not employ abdominal puncture for diagnosis. Operative intervention is contraindicated in the stage of shock, e.g., during the first two or three days. It is likewise contraindicated during the stage of diffuse peritoneal inflammation, since the exudate does not cause paralysis of the intestine and the intervention at this stage diminishes the resistance of the organism and increases the toxicity of the pneumococcus. Operation is indicated in the stage of encapsulation. Auto vaccines, serums and roentgen therapy during the first few days have not so far given definite results.

*Eosinophilia After Intravenous Injections of Oil II Relation of Bone Marrow and Significance of Spleen J Engelbreth Holm and C C Winkel Smith Statistical Assistance by G Rasch—p 589

Eosinophilia After Intravenous Injections of Oil—Engelbreth-Holm and Smith conclude that the eosinophilia established in the blood after intravenous injections of oil is probably due to an effect on the bone marrow with new formation of eosinophil leukocytes in the marrow. During the course of this new formation the content of eosinophil cells in the bone marrow seems to undergo certain shifts. The curve is wavy, with peaks on the fifth and the tenth day after start of the oil injections and above normal during the entire period. The curve may perhaps be explained as the resultant of two curves, one expressing the increased production of cells in the marrow, the other the increased transmission of cells to the blood stream, the two curves having a common peak but not running parallel. A possible relation between the number of cells in the marrow and in the blood can be established only by examination in series or by repeated frequent examinations. Intact spleen function is not necessary for the development of eosinophilia.

*Chronic Fibrous Adhesive Pericarditis (Symphysis of Pericardium) Report on Fifty Seven Necropsy Cases H C A Lassen—p 567

Intrapelvic Pressure and Clinical Significance J Olesen—p 511

*Investigations on Blood Sedimentation Reaction in Stored Blood S Christensen and S A Holbøll—p 576

Chronic Fibrous Adhesive Pericarditis—Lassen says that of the fifty-seven cases (in thirty-two men and twenty-five women, about half of them over 60 years of age, ten under 40) out of 1,601 necropsies from the medical division of the Kommunehospital, or between 2 and 3 per cent, the postmortem diagnosis was total symphysis of the pericardium in forty-two and almost complete obliteration of the pericardial sac in fifteen. In twenty cases there was history of rheumatic fever, in two of pulmonary tuberculosis and in nine of syphilis or active syphilitic infection at the time of death. In the majority, cardiac or circulatory disturbances dominated on final hospitalization. In thirty-three, cardiac insufficiency was assigned as the cause of death, in seventeen as a contributing cause, and in seven no sign of cardiac insufficiency was noted. The twelve cases are described in which the author believes that the diagnosis of cardiac symphysis might have been made clinically or suspected. He says that study of the operability of the fifty-seven patients on the basis of all available information indicates that probably none could have been operated on successfully. Two additional cases with clinical diagnosis of symphysis of the pericardium are reported in which operation is being considered.

Blood Sedimentation Reaction in Stored Blood—Christensen and Holbøll find that even after from one to three hours the sedimentation values are lowered by about 10 per cent and after six hours by about 20 per cent. The reduction varies somewhat with different specimens. After twenty-four hours' storage the sedimentation values are always very low, on the average about one third of the values in fresh blood. Covering the blood with liquid petrolatum does not prevent the reduction of the sedimentation values of stored blood.

THE PATHOLOGY OF ANGIOID STREAKS IN THE FUNDUS OCULI

CHAIRMAN'S ADDRESS

WILLIAM L. BENEDICT, M.D.
ROCHESTER, MINN.

According to Treacher Collins,¹ the first recorded case of what is now known as angiod streaks in the fundus oculi was that presented at a meeting of the Ophthalmological Society of the United Kingdom by Robert W. Dooyne in 1889. This case was reported in the *Transactions of the Ophthalmological Society of the United Kingdom* in September 1889, and a colored illustration of the fundus accompanied the report.

Dooyne's patient had suffered an injury to his right eye from a block of wood six weeks prior to examination. Central vision was lost, but he seemed to have good peripheral vision (RV = 6/60). The description of the fundus was briefly given as follows: "In the right eye there is an extensive choroidal hemorrhage, which is now clearing up, leaving patches of atrophy, such as are seen in the left eye. In all directions throughout the choroid of both eyes, especially around the disks, are irregular jagged lines, nearly all deeply pigmented. The irregularities and jags in their outline exactly correspond in most places, and are probably due to rupture of the pigment layer of the retina." After the choroidal hemorrhage had cleared up, which required a few weeks, the other condition remained the same and vision improved to 6/18.

In 1892 Plange² reported a condition which he thought had not previously been described which "bore a certain similarity to the disease known as retinitis striata, but in etiology resembled retinitis proliferans." The patient was a woman, aged 38. Both eyes were affected. The streaks radiating from the disk ended in retinal hemorrhages. He noted a "deposition of pigment in striae in the retina after hemorrhage, followed by changes, probably hyperplastic, in the supporting fibers of Muller."

After reading Plange's article, Knapp³ thought that the explanation of the condition in his case was similar. Knapp had noted and sketched pigmented jagged lines in the fundi of a patient he had seen two years previously. He had offered no explanation of this occurrence. In his report, printed in the same volume of

the *Archives of Ophthalmology* and in the pages immediately following Plange's article, he wrote: "In this communication it has not been my intention to discuss in detail the changes extravasated blood may undergo in the retina, but to furnish a second case of the rare and puzzling formation of dark angiod streaks which Dr. Plange has described." From this statement it would seem that Knapp was either not aware of Dooyne's report or believed that Plange's description better fitted his case. As a matter of fact, Collins did not call attention to Dooyne's report until 1923, but in his paper he referred to the condition described by Dooyne as "angiod streaks," a term first applied by Knapp and now quite generally used to denote this particular picture.

When one compares the description in Dooyne's case with that in Plange's, it seems probable that the changes in the fundi may well have been brought about by different causes. In Dooyne's case, in which injury had occurred, after the choroidal hemorrhage had disappeared the jagged lines were free from hemorrhage and appeared as ruptures of a thin membrane, which allowed a clearer vision of the deeper lying pigmented tissue. In Plange's case there appeared to be a deposit of pigment in striae in the retina after hemorrhage. In the one case the streaks were thought to be due to absence of pigment whereas, in the other, there was deposited a pigment of extraneous origin, probably, but not surely, from extravasated blood.

Many case reports published during the next thirty-six years gave valuable information regarding the nature of angiod streaks and their association with pathologic changes in the choroid and hemorrhages in the retina. A few cases were described in which hemorrhages were not found on repeated examination. I have frequently examined one patient who has been under observation for eight years and have never seen hemorrhages in that fundi.⁴ The streaks are always accompanied by choroidal changes of significant extent, although visual acuity may not be seriously impaired unless the macular region is involved. Angiod streaks are found only in adults, having never been observed in children, and they are almost always bilateral.

Explanations of angiod streaks have been offered by various authors, and while these explanations have been influenced somewhat by their own ophthalmoscopic observation, they have been based primarily on the views of previous writers. As the disease does not require enucleation of the eye, pathologic examinations of undoubted cases have not been made. Conceptions of the histopathology of angiod streaks have therefore been constructed from the ophthalmoscopic appearance of the fundi, the course of the disease, the effects on vision, and constitutional disturbances.

From the Section on Ophthalmology, the Mayo Clinic.
Read before the Section on Ophthalmology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

4. Benedict, W. L. and Montgomery, Hamilton. Pseudoxanthoma Elasticum and Angiod Streaks. *Am. J. Ophth.* 18: 205-212 (March) 1933.

Collins¹ in 1923 referred to the pathologic papers of Lister and of Magitot. The condition described by Lister pathologically had not been seen clinically, and the case described clinically as well as pathologically by Magitot was by no means a typical one of angioid streaks. Collins's conception of the pathology of the streaks was of a deposition of hematogenous pigment derived from subchoroidal hemorrhage in the perivascular spaces of the short ciliary arteries composing the circle of Zinn, the branches proceeding from it being filled with, and blocked by, blood pigment (hematoidin and hemosiderin crystals).

Verhoeff⁵ in 1928, in a paper read before this section, according to Zentmayer,⁶ who discussed his paper, gave "an exhaustive detailed description of the microscopic changes in an eye that had been enucleated following an iridectomy undertaken for the relief of secondary glaucoma consequent on an ulcerative keratitis. The period over which the eye had been inflamed was more than three months. No ophthalmoscopic examination of this eye had been made by Dr. Verhoeff, nor was any record of such examination obtainable. Macroscopically, after enucleation, dark angioid streaks were seen over a portion of the fundus. In the fellow eye, the fundus of which was examined, no angioid streaks were seen, but changes were present around the optic disk in the nature of a gray zone with two white streaks extending therefrom." On microscopic examination of the enucleated eye, Verhoeff found marked fibrosis of the choroid in the whole of the inner lower half of the fundus, and the inner surface of the fibrosed choroid showed many projections of various sizes. "A segment of the fundus, from which the retina had been peeled off, showed perfectly typical dark angioid streaks which branched and anastomosed. Microscopic examination of the eye showed the streaks to be ridges comprising the inner layers of the choroid, produced by cicatricial contraction of fibrous tissue which had replaced the deeper layers. The fibrosis involved almost uniformly about one-half the total extent of the choroid and was associated with extensive obliteration of the vessels and a few subchoroidal hemorrhagic extravasations." On the basis of the observations in his case, Verhoeff suggested as a descriptive designation for the condition now known as angioid streaks the term "fibrosis choroideae corrugans".

Pathologic changes in the choroid have been noted in nearly all reports of cases of angioid streaks of the fundus oculi. These changes are in many cases quite extensive and associated with hemorrhages in the retina and choroid. The fact that angioid streaks appear in eyes in which hemorrhages are not seen at the time of examination does not prove that the streaks can be formed without hemorrhage. On the other hand there is as yet no definite proof that extravascular extravasation of blood has any definite part in the formation of the streaks. Whether or not ridges formed by fibrosis in the outer layers of the choroid are always present can be decided only after further microscopic examination of eyes which undoubtedly have angioid streaks.

Gronblad⁷ in 1929 and in 1932 called attention to the association of angioid streaks and pseudoxanthoma elasticum. This association has been verified by numerous subsequent observations. These reports gave rise to speculation as to the possibility of angioid streaks in the fundus oculi being due to changes in the glass membrane following some degenerative process. A pathologic report on an eye known to contain angioid streaks has not been made since the association of angioid streaks and pseudoxanthoma elasticum was first noted, but at least two explanations have been offered. Clay⁸ thought that "short posterior ciliary veins passing through the sclera in an anomalous manner become thrombosed mechanically by the increase in the fibroelastic tissue of the sclera, resulting in the appearance of hemorrhages, exudates and streaks corresponding to the vessels involved." About the same time, Wasseenaar⁹ explained the streaks as abnormal vessels which find their way between the two blades of the embryologic eye and hence are of congenital origin. Others have proffered theories of streak formation that are only modifications of explanations previously made and are based entirely on ophthalmoscopic examination and speculation. In April 1937 Finnerud and Nomland¹⁰ reported cases of the three possible combinations of pseudoxanthoma elasticum and angioid streaks of the retina: (1) pseudoxanthoma and angioid streaks, (2) pseudoxanthoma alone and (3) angioid streaks alone. They demonstrated by staining methods, by incineration, by quantitative chemical analysis and by microchemical means that the degenerated elastic tissue in pseudoxanthoma elasticum is richly infiltrated with calcium and that this calcium occurs in the form of calcium phosphate.

Fundus of left eye showing angioid streaks and peripapillary choroiditis

In September 1936 I enucleated the blind right eye, for absolute glaucoma, of a patient who had typical angioid streaks in the left eye and pseudoxanthoma elasticum of the sides of the neck and in the axillary folds. A report of this case is as follows:

REPORT OF CASE

A man, aged 46, came to the clinic for treatment of a blind, painful eye. After he had been hunting all day in November 1933, his eyes felt sore and, on returning home, he put a proprietary ointment in his eyes and went to sleep. Next morning when he began to read the paper he noticed that his left eye was blind. He had no pain or discomfort. This eye remained blind for about six months and then sight was gradually recovered. The patient's eyes were not examined by an ophthalmologist. In June 1936 he then noted a disturbance of vision in his right eye. Flickering lights were followed by shadows, which gradually became more dense until only light perception was present two months later. Early in September the right eye became inflamed and painful. The pain increased in severity and spread over the right maxillary and mandibular region.

The patient was suffering severe pain about the right eye when admitted to the clinic. Vision in the right eye was light

perception only, in the left eye 6/15 without glasses. The right eye showed acute congestive glaucoma, the cornea being so cloudy that ophthalmoscopic examination was impossible. The tension was 112 mm of mercury (Schiotz), the left eye was free from inflammation, the tension being 14 mm of mercury. The left cornea was clear and the fundus could be clearly seen. The disk was full and slightly pale and the retinal vessels showed moderate sclerosis of the hypertensive type. There was no retinitis. About the disk was an angioid ring from which streaks radiated in jagged lines toward the periphery, as shown in the accompanying illustration. The fundus was photographed and the streaks were clearly demonstrated. General examination revealed severe hypertension with definite arteriosclerosis. There were no symptoms referable to the heart or kidneys. The patient's father had died of apoplexy at the age of 55, his mother had died of heart trouble at 59. Six siblings all had high blood pressure, and all were in broken health by the fourth or fifth decade of life.

The patient's blood pressure was high. On the day he arrived it was 242 mm of mercury systolic and 154 diastolic and the pulse rate was 132 beats per minute. On the following day it was 228 systolic and 150 diastolic and the pulse rate was 114, on the third day the blood pressure was 250 systolic and 150 diastolic. The right eye was enucleated under sodium ethyl (1 methyl butyl) thiobarbiturate anesthesia. Healing of the socket was satisfactory. On September 19, correction for the left eye was given: S + 0.50, cyl + 0.25, axis 165, vision 6/7.

The enucleated eye was placed in solution of formaldehyde for fixation. After two days it was divided at the equator and the posterior segment was examined for angioid streaks. By use of a Zeiss binocular magnifier and a Shahan lamp angioid streaks could clearly be seen when the light was applied from the front. By transradiation the streaks could not be distinguished from the shadows of the vessels in the sclera and choroid. Attempts were made to photograph the streaks by reflected light, by transradiation and by infra-red light.

Photographs made by reflected light showed the streaks rather faintly. They appeared as jagged dark lines radiating from an incomplete ring near the disk and extended from 2 to 4 disk diameters beyond the disk margin. The posterior half of the eye was embedded in celloidin and sectioned in the equatorial plane. It was thought that, by making sections which showed tissue completely surrounding the disk, any vascular change or anomaly could be detected and followed through serial sections.

Microscopic examination of these sections however, failed to show any pathologic changes that could be identified as angioid streaks. The retinal structures appeared practically normal, except for numerous small vacuoles resulting from fixation and embedding. The retinal vessels were patent and showed no sclerosis. There was no retinal hemorrhage. The choroid showed perivascular lymphocytic infiltration about many of its vessels and heavy deposits of pigment surrounding the vessels and nerves. Sclerosis and obliteration of the choroidal vessels were not seen. The veins were large and thin walled. The arteries were all patent and their walls were not thickened. The lamina vitrea was regular except for a few very small hyaloid nodules. There was some fibrosis of the choroid, but folding or projections of the inner layer of the choroid were not present. There was perivascular lymphocytic infiltration in the episcleral vessels, most marked in the anterior sections, and a considerable amount of pigment about the vessels and nerves traversing the sclera. In the hematoxylin stained sections there was no evidence of increased calcium in the choroid or the lamina vitrea.

None of the proffered explanations of angioid streaks could be confirmed by microscopic examination of the sections of the enucleated eye. There were no thrombosed vessels about the zonule of Zinn, as suggested by Collins and Clay, nor were there any abnormal vessels, as suggested by Wassenaar. Some fibrosis was present, particularly about the disk, but folds or projections were not found, probably as Dr Verhoeff (who kindly examined several sections) suggested because they showed the choroid cut obliquely, so that the streaks would be cut obliquely and no doubt partly longitudinally and would therefore be difficult to recognize. Further doubt of the presence of folds in the choroid was found in the fact that photographs

taken by transmitted light failed to show any streaks or lines that corresponded to those seen in photographs taken by reflected light.

Rents in the pigment epithelium, an explanation offered by some authors, could not be confirmed. The retina appeared to be normal but was separated from its base by manipulation in attempts to get clearer photographs of the streaks before fixation was complete. Increased amounts of calcium found by Finnerud and Nomland in pseudoxanthoma elasticum could not be demonstrated in the hematoxylin stained sections of the eye.

The cause of the patient's temporary blindness in the left eye in 1933 could not be determined. Because of the sudden onset of this blindness and the gradual but slow recovery of vision, one may presume that a hemorrhage of the retina or choroid was responsible. One cannot assume however, that if a hemorrhage occurred it had any connection with the formation of the angioid streaks which were first seen three years later. In spite of the patient's family history of vascular disease and his high blood pressure, the fundus of his enucleated eye did not show the retinitis of hypertension. There was no marked change in the macular region of the left eye, as proved by a nearly normal visual acuity with glasses.

A definite cause could not be found for the acute glaucoma of the right eye, but as the failure of vision in this eye was gradual, as contrasted with the sudden loss of vision in the left eye, it may be assumed that the intra-ocular tension had risen slowly to the point of producing blindness two months before the onset of pain. The absence of microscopic evidence of hemorrhage in the enucleated eye precluded the possibility of severe hemorrhage as the cause of the blindness.

EPIDEMIC DIARRHEA OF THE NEW-BORN

I PRELIMINARY CONSIDERATIONS ON OUTBREAKS OF HIGHLY FATAL DIARRHEA OF UNDETER- MINED ETIOLOGY AMONG NEW-BORN BABIES IN HOSPITAL NURSERIES

JOHN L. RICE, MD
WILLIAM H. BEST, MD
SAMUEL FRANT, MD
AND
HAROLD ABRAMSON, MD
NEW YORK

From time to time, reports appear in the medical literature on outbreaks of diarrheal disorders among residents either of public institutions or of localized community areas. In most instances these recorded epidemics have been of known etiology and have involved adults as well as infants and older children. However, surprisingly few reports have been published on outbreaks of infectious diarrhea solely involving groups of new-born babies. It is of interest, moreover, that instances of such epidemics have been recorded only within recent years. It is therefore our purpose to present a summary of our experiences during the past three years with epidemics of highly fatal diarrhea affecting new-born infants in the nurseries of lying-in institutions in New York City.

THE SITUATION OUTSIDE NEW YORK CITY

In view of the scanty literature on the problem, it was deemed worthwhile to review the essential facts of the few reported epidemics. For this purpose, table 1 is presented, giving in chronologic order a summary

From the Department of Health, New York City. Dr. John L. Rice, Commissioner.

Read before the Section on Pediatrics at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

of outbreaks of diarrhea of the new-born in localities other than New York City¹

In these reported epidemics certain common clinical features predominate, namely, the presence of severe diarrhea, dehydration and toxicity without manifest evidence of parenteral infection, and an unusually high average case fatality rate of about 45 per cent, a figure closely comparable, as will be pointed out subsequently, to the case fatality rate in our series of cases. In addition, attention should be called to the few tissue changes that have been noted at autopsy and to the diversified array of morbid agents to which the various epidemics have been ascribed.

As far as we have been able to ascertain, aside from the foregoing reports and those by Barenberg and his co-workers² and by Murphy and Mallozzi,³ the details

born," meriting consideration apart from other primary and secondary diarrheal disorders of infancy. We base our opinion on the remarkable similarity in the clinical picture, clinical course and mode of spread of the epidemics in the nurseries of the various hospitals, the specificity of the age group involved, the presence of a definite period of incubation, the constantly high morbidity and mortality rates, the similar and surprisingly few tissue changes that have been found at necropsy, and the difficulty at present of culturing the etiologic agent by usual routine bacteriologic methods.

Table 2 presents in chronological order the essential details of the epidemics of diarrhea of the new-born in New York City. The data are not to be considered as either complete or final, the reasons for which will be brought out subsequently. However, they are the clos-

of which will be included in our general discussion, no further communications on the problem of infectious diarrhea of the new-born have appeared in the recent literature. It is true that in 1928 the Dicks and Williams³ reported an epidemic of primary acute enteritis associated with mastoiditis among the infants at the Cradle, Evanston, Ill. The Morgan bacillus was considered the etiologic factor in this outbreak, but a review of the fatal cases described shows that many of the infants attacked were well beyond the new-born period.

THE SITUATION IN NEW YORK CITY

From our observations of the various epidemics that have occurred within the city of New York, and from such added information as can be gleaned from the literature, it is our opinion that we are dealing with a new clinical entity, "epidemic diarrhea of the new-

est approximations that were possible, as the syndrome has not been a reportable condition.

During the period from July 1934 to December 1936 inclusive, a total of 3,769 babies were delivered at the eleven lying-in institutions at the times designated in the table. Ninety-seven of these babies were still born. Of the remaining 3,672 live-born babies, 138 died shortly after birth from neonatal causes of death such as prematurity, birth injuries, atelectasis, asphyxia and congenital malformations. There were thus about twenty-six stillbirths and thirty-eight neonatal deaths per thousand live births at the hospitals with which we are concerned, as compared with rates of fifty stillbirths and twenty-eight neonatal deaths in infants under 1 month of age per thousand live births for New York City during the same period.

Among the 3,672 live-born babies there occurred 505 known cases of epidemic diarrhea of the new-born, with a morbidity rate of 14 per cent. Two hundred and thirty-four known deaths occurred, a mortality rate of 7 per cent. The case fatality rate was exceedingly

high, namely, 46 per cent. It should be emphasized that these rates were exclusive of the "usual" neonatal mortality from causes other than epidemic diarrhea.

EPIDEMIOLOGY

Age—The disorder specifically involves new-born infants during the first two or three weeks of life. Of those babies who took ill after discharge from an infected nursery, many were readmitted subsequently

incidence of the disease with respect to respiratory infections of the fall-winter months or with respect to diarrheal disorders of the spring-summer months.

It is of interest to observe the closeness of the various epidemics with reference to time and season, and the fact that the secondary or recurrent outbreaks experienced by hospitals A, C, D and G took place after an apparent interval-free or latent period of from four to five months. It should also be noted

* Names of hospitals have been omitted and indicated by letters since with the exceptions of hospitals C and F no published reports on outbreaks have appeared in the literature. The numbers in parentheses denote first, second and third outbreaks in the same institution.

† It is of interest to note that no fatal cases occurred in this hospital. The only explanation that can be offered is that the first few cases of the disorder were immediately recognized. The maternity and new-born services were promptly closed to further admissions and early and intensive treatment was instituted in all sick infants. The clinical picture was similar to that observed in other hospitals.

to open pediatric wards and were cared for by the regular nursing staffs. At no time did instances of cross infection appear among the older infants and children in the ward or among the adult personnel, nor were there secondary cases among the siblings or adult members of the ill infant's family.

Sex—There is no apparent sex difference in the incidence of the disorder.

Race—Babies of all races and nationalities have been involved in the epidemics. This factor varied with the section of the city in which the affected hospital was situated.

Season—An analysis of the data with respect to seasonal variation of the disorder is shown in table 3. No definite relationship can be made out between the

that, with the exception of Richmond, all boroughs of the city had outbreaks of the disorder.

Climate—It is to be noted that epidemics of the disorder have been observed particularly in cities that are situated within the north temperate zone. They are Seattle, Chicago, Toronto, Buffalo, New York City and its adjacent areas, perhaps Baltimore,⁴ Memphis, Edinburgh and Garches, near Paris, France.

Socio-Economic Conditions—The outbreaks occurred mostly in the ward services. However, in two outbreaks in which the ward and private facilities were in close proximity, babies of mothers in private pavilions also were infected.

⁴ Personal communications to the authors from Dr E L Holt Jr of Johns Hopkins Hospital, Baltimore.

Nutrition—No definite relationship seems to exist between the state of nutrition of the infants and the incidence of infection, although it is our impression that prematurely and immaturely born infants and those suffering from other abnormalities of birth are more particularly prone to the disease

Feeding—Both breast fed and artificially fed infants appeared to be equally susceptible to the disorder With respect to the breast fed infants this statement deserves further comment, since in all hospitals it has become routine to give new-born infants some form of additional food or fluid during the first week or longer in order to prevent early weight loss This modern pediatric practice has made the old distinction between breast fed and artificially fed infants much less sharp

SYMPTOMATOLOGY

The clinical manifestations of the disorder are most interesting At times the condition may be preceded for one or two days by prodromal symptoms such as occasional vomiting, arrested weight accretion, listlessness and refusal of feedings More often, however, the onset is acute and the clinical picture rapid in its

TABLE 3—Seasonal Morbidity and Mortality in Epidemics of Diarrhea of the New-Born

Winter	457 }	92 }	20.1 }	34 }	7.4 }
Totals	3 672	500	13.6	234	6.4

course We are concerned essentially with a group of new-born babies in the usual hospital nursery The babies seem to be healthy and thriving normally when it is noted that one of them is unusually drowsy, being awakened with difficulty and having a short, feeble cry The body temperatures may vary from 99 to 100 F, occasionally somewhat higher It is next observed that the baby has had a characteristic very watery yellow stool, less frequently yellowish brown or greenish, containing no mucus, pus or blood Occasional vomiting may occur, abdominal distention may become a disturbing feature

The general appearance of the baby soon changes from that of a previously healthy nursing to that of a markedly dehydrated and marantic infant in shock Watery stools of increasing frequency occur and weight losses amounting to as much as a pound or more within a period of twenty-four hours may be noted In a severe case death of the baby may occur in one day, or the infant may linger on for from five to seven days, becoming semicomatose and perhaps developing in the interim secondary terminal complications such as otitis media and bronchopneumonia In milder cases recovery is heralded by gradually subsiding temperature, diminution in the frequency of stools, arrested weight loss and desire for food

In brief, the clinical picture is that of an acute intestinal toxosis, probably of primary origin, accompanied by watery yellow stools, abdominal distention, severe degrees of dehydration, rapid weight loss, little or no

temperature reactions except terminally or with the occurrence of secondary complications, and marked toxicity, drowsiness and shock Vomiting occurs infrequently Blood, mucus or pus in the stools and early fever are not usual features of the disorder Neurologic signs and symptoms are rare Laboratory examinations of the blood reveal abnormally high concentrations as well as severe degrees of acidosis In general, the prognosis is very unfavorable

MODE OF SPREAD

With the initial case serving as the focus of infection, additional cases occur, usually involving infants lying in adjacent bassinets The incubation period of the disorder appears to be a variable one Many infants showed manifest signs of the disease but two days after having been placed in infected nurseries, other babies became ill as late as the twentieth day of postnatal life The majority of cases occurred within these limits The spread of the infection is an irregular one, the babies coming down in groups of two or three or more Often many days, even as long as a week, may elapse between the occurrence of new groups of cases This is one of the misleading and distressing features of these epidemics During these interval free or latent periods the outbreak has often been considered at an end and the nurseries reopened to admissions of new babies, thereby providing further soil for the perpetuation of the epidemic In the hospitals that were investigated the outbreaks were never fully controlled until the maternity services were completely closed to new admissions, the babies discharged after a prolonged period of observation, and the obstetric and nursery quarters completely renovated

Many babies took ill after discharge from the hospital in apparently good condition These babies were readmitted to the pediatric services of the various hospitals Additional cases were found by follow-up home visits as well as by checking the death certificates of infants dying under 1 month of age throughout the city and tracing the deaths back to the institution of birth, regardless of the cause of death as given In this connection it is well to call attention to the observation of the members of the White House Conference on Child Health and Protection with reference to the meaningless diagnoses that are often recorded as being the cause of death of infants during the new-born period of life⁵

PATHOLOGY

Postmortem examination of the new-born infants who died during the course of the various epidemics revealed a marked lack of pathologic lesions As is not unusual in infectious diseases during the new-born period, the clinical severity of the disease was entirely out of proportion to the few induced tissue changes However, the observations of other investigators in this field of diseases of the new-born indicate similar experiences For example, Cruickshanks⁶ found in studies on gastro-intestinal disease as a cause of neonatal death that postmortem examinations of new born infants with clinical histories of vomiting, diarrhea and abnormal stools seldom showed evidences of a true enteritis Histologic examinations likewise failed to

5 White House Conference on Child Health and Protection 1A Inadequacy of Present Knowledge in Growth and Development of the Child, Part I General Considerations section 1 Medical Service 1937 pp 366-370

substantiate such a diagnosis. Von Reuss⁷ also stresses the fact that, in infectious diseases of the alimentary tract of the new-born, local signs of inflammatory involvement of the intestinal mucosa are rarely encountered but that the significance of the digestive tract as a portal of entry for pathogenic organisms, especially during the new-born period, must not be underestimated.

In our series of cases the pathologic lesions consisted essentially of some congestion of the surface vessels of the intestinal tract, congestion of Peyer's patches of the ileum and occasional hemorrhagic areas, the mucous membranes appeared normal. There was frequently encountered some swelling of mesenteric lymph nodes. Other occasional manifestations were otitis media, parenchymatous degeneration of the liver, kidneys and heart, bronchopneumonia, and congestion of the dural and meningeal vessels. In general, however, no pathologic lesions of outstanding significance were found.

BACTERIOLOGY

Repeated attempts made to isolate the etiologic agent of the disorder were unsuccessful. Recovery of organisms was attempted from the gastro-intestinal tract and the upper respiratory passages. However, numerous cultures of the stools and of the nasal and pharyngeal secretions of the sick infants gave very indefinite results. Similar cultures taken from the nurses, physicians, mothers and other maternity and nursery service personnel also failed to reveal a causative organism. In the nose and throat cultures the usual varied flora of the upper respiratory passages was encountered, from the stools the organisms most frequently isolated were bacilli of the coli, proteus and pyocyanus groups. Occasionally infectious agents of the dysentery group of bacteria were found, but the results were highly inconsistent and could not be confirmed either by reexamination or by agglutination tests during various stages of the disease or after recovery. Blood culture studies and agglutination tests for organisms of the typhoid, paratyphoid, salmonella and abortus groups were likewise negative. Virus studies also failed to shed any light on the nature of the morbid agent. In passing, it should be mentioned that in one outbreak (hospital F) a monilium was isolated from the stools of one infant, a finding of interest in connection with the report of Durand¹.

As has been shown by the work of Hall and O'Toole⁸ and of Snyder,⁹ these indefinite results stress the complexity of the task of isolating and identifying bacteria in the constantly changing and varied intestinal flora of new-born infants. Poole and Cooley¹⁰ believe that the lack of uniformity of results is dependent on the following factors: (1) the technic that is used in procuring material for culture, (2) the type of patient under observation and the condition from which he is suffering, (3) the seasonal variation of diarrheal disorders and (4) the geographic locality of the occurrence of an epidemic. In addition, Gerstley¹¹ has called attention

to the well known differences between the intestinal floras of artificially and of breast fed infants.

Many difficulties are also encountered in bacteriologic studies on nasal and pharyngeal cultures of the new-born. Kneeland¹² found that infants in a maternity hospital acquired much of the normal flora of the upper respiratory passages during the first two weeks of life and that during that period there was a significant absence of pneumococci, hemolytic streptococci and influenza bacilli. In 80 per cent of the thirty new-born babies that were examined, initial throat cultures showed no growth until after the first feeding. Subsequently, the predominating organism was the nonhemolytic streptococcus (60 per cent), with *Staphylococcus albus* (27 per cent) next in frequency. Cultures of nasal secretions likewise showed no growth on the first post-natal day in 85 per cent of the babies and in 40 per cent on the second day. The predominating organism on the first positive nasal culture was *Staphylococcus albus* (76 per cent).

In this connection, mention should also be made of the investigations of Potter and Abel¹³ on the surface bacteria of the new-born. Although a few babies showed skin sterility at birth, the majority were non-sterile, *Staphylococcus albus* and *Bacillus coli* being isolated most frequently.

In general one cannot postulate a common etiology for enteric diseases in infancy. Yet the striking similarity in the clinical features of the various epidemics that we have observed lead us to believe that we are concerned with a common etiology in these outbreaks.

TREATMENT

As far as treatment of the sick babies is concerned, the results were uniformly disappointing. In general, the infants did not respond satisfactorily to the recognized modes of therapy in diarrheal disorders. Limited periods of starvation, fluid replacements, blood transfusions and step-up methods of feeding failed in most instances to stem the course of the disease. However, somewhat better results were obtained when the disorder was recognized early and when therapeutic measures were immediately begun and intensively pushed.

CONTROL AND PREVENTION

It is not within the scope of this report to consider in detail methods for the control and prevention of the disease. This aspect of the problem will be discussed fully in another communication. It should be emphasized, however, that the commonly employed procedures in the control of communicable diseases cannot be satisfactorily applied to this problem. The present arrangement of maternity and new-born services with the constantly changing and shifting populations requires special technics for the prevention and control of the spread of infection.

For the present it will suffice to state that the recognition of the first case of epidemic diarrhea of the new-born in a nursery necessitates immediate isolation of the sick infant. In addition, the infected nursery should be closed and the maternity service suspended until it can be definitely ascertained that no further cases will occur. Provisions should be made for the isolation of all secondary cases, and all new-born contacts should be

observed for a minimal period of three weeks before being discharged as normal. In this way, scattering of sick infants will be avoided and early treatment may be begun in new cases. The adoption of a technic of "aseptic nursing" is of importance.

Measures should also be taken for the examination and bacteriologic investigation of all maternity and new-born service personnel, as well as of mothers. In addition, a thorough study should be made of the milk supply and accessory formula preparations and all formula room equipment. Likewise, a complete inspection of the sanitary facilities is indicated. It has been our experience that in institutions where prompt, vigorous and complete measures were employed, morbidity and mortality from the disease were lowest. Half-way measures served only to accomplish the opposite effect.

As a preliminary measure in the control of the disease, the Sanitary Code of New York City was amended to include as a reportable condition all cases of diarrhea in the new-born (up to the age of 3 weeks) in lying-in institutions.

SUMMARY

This report is a preliminary analysis of outbreaks of highly fatal diarrhea that have occurred among new-born babies in the nurseries of eleven lying-in institutions of New York City from July 1934 to December 1936. Among 3,672 live-born babies, 505 cases of the disease occurred, a morbidity rate of 14 per cent. Of the sick infants 234 died, a mortality rate of 64 per cent. The case fatality rate was 46 per cent. Extensive bacteriologic investigations failed to reveal the inciting agent of the disorder. Autopsy did not shed any definite light on the pathogenesis of the disease.

The clinical syndrome was characterized by signs of acute intestinal toxæmia, probably of primary origin, and was accompanied by the symptom train of frequent watery yellow stools, abdominal distention, severe dehydration, drowsiness and acidosis, rapid weight loss, little temperature reaction, marked toxicity and prostration. Vomiting occurred occasionally, blood, pus or mucus in the stools was infrequent. The main complications were terminal otitis media and bronchopneumonia.

From our observations of the various outbreaks, and from a careful search of the literature, it is our present impression that we are dealing with a well defined clinical entity affecting infants of the new-born period of life, deserving consideration apart from other diarrheal disturbances of infancy. We feel that the condition is more widespread than a survey of the literature would lead one to believe.

ABSTRACT OF DISCUSSION

DR HUGH L DWYER, Kansas City, Mo. There are several interesting features in the severe form of diarrhea of the new-born observed by the authors. All physicians have seen diarrhea in early life go on to a fatal termination, with little or no postmortem manifestation to explain it, and with bacteriologic studies of the discharges that were likewise negative or inconsistent and therefore unsatisfactory. I have always assumed that the condition was some form of bacillary dysentery, because in my experience with clinical dysentery in older infants the stool examinations do not always reveal the nature of the infectious agent. In the present report I note that the Flexner and Morgan types of dysentery bacilli were found in a few cases. In my experience negative bacteriologic studies and the absence of significant postmortem appearances are not unusual in the highly fatal diarrhea of infancy—if we are talking about the same disease. The epidemiologic aspect of this

study is of great interest. Of all the nurseries in New York City, this condition was observed in only eleven. My own experience with diarrhea in the new-born is limited to an occasional outbreak in a nursery and small epidemics in infants' homes, and for this reason, probably, I have not been impressed with the high morbidity rate. One cannot appreciate the epidemic nature of this condition without an opportunity to observe reports emanating from many hospitals in a metropolis—an experience that the authors have had. The fact that the disease is confined to the nursery for new-born infants, can be transmitted to another new-born infant in an adjacent bassinets but has not been reported in older infants in the same home or in the ward to which the ill infant is transferred is a feature that needs further explanation. It is difficult to conceive of an infectious agent having any such respect for age periods in early life. With a morbidity rate of 14 per cent and a mortality rate of 64 per cent of all infants born in eleven institutions, this disease, from a public health standpoint, assumes proportions not even closely approximated by all other neonatal diseases. This mortality rate is double the neonatal mortality in the United States birth registration area from all causes. I hope that we hear further from Dr Rice and his collaborators as well as from other observers, especially with reference to the cause of the disease and whether it is limited to the new-born.

DR JOHN AIKMAN, Rochester, N Y. The explosive character of these epidemics was well shown in the Genesee Hospital at Rochester in January 1936. In a maternity nursery of thirty-one beds, no deaths had occurred in one year. With but little warning several infants acquired diarrhea, and four deaths occurred in four days. At the same time a child of 2 months died of gastro-enteritis in the children's ward, which is located in another wing of the hospital. This child was born in New York City and at 4 weeks of age, after moving to Rochester, developed diarrhea which did not yield to any form of treatment. Of the four cases in maternity, three occurred in premature infants who had always fed poorly, but the other was in a full-term normal child that died after four days of illness. At the same time, six other infants developed diarrhea and one died. One other fatal case developed later. Of twelve patients seven died, a case fatality rate of 58 per cent. Most of our trouble occurred within ten days and measures for investigation and limiting the epidemic proved successful. Dr Rudolph Angell made an excellent survey of the epidemic. Laboratory studies did not point to any definite bacterial factor. Five of our cases came to autopsy and all gave evidence of bronchopneumonia. I believe that we were dealing with an epidemic similar to the epidemics so well described by Dr Rice and his associates and that our trouble may have been brought to us from New York City, where epidemics were then in existence. The majority of the cases were under the care of different private physicians. As no one physician saw all the cases develop, a delay occurred before the epidemic character was realized. This could be avoided if nurses in charge of maternity divisions immediately reported all cases of diarrhea to the main office. The formulas for the nursery had been prepared in the formula room, adjoining the children's ward, in another building. All milk had been boiled, but we found that some of the bottles were kept in refrigerators for twenty-four hours. We wondered how efficient our modern refrigerators were and had frequent temperature readings inside the food chambers. They varied from 46 to 54 degrees. The average was about 50 degrees, which we considered too high. Since the epidemic the temperatures have been kept at a lower level and the refrigerators are frequently inspected. Formulas for the maternity ward will in the future be prepared in a formula room in the maternity department. These epidemics naturally shake the confidence of the public, and maternity departments suffer as a result. As the present authors have pointed out, this is a new problem and one that is likely to occur at any time. All cases of diarrhea in new born infants require strict isolation and careful investigation. The section is fortunate in having the subject presented in such an excellent manner.

DR. WALTER D LUDLUM, Brooklyn. I am always disappointed when I hear a paper which stops short of the treatment angle, and that has not been much stressed. The authors

incidentally remarked that the distinction between breast-fed babies and bottle-fed babies was far less distinct than it formerly was. In the city of New York, practically all babies are at least partially bottle fed, they all have bottles with nipples on them. In most nurseries, one nurse goes from baby to baby and puts the nipples on. That nurse may have an infected hand. My assumption is very strong that the method of transmission is from bottle nipples and by the hand of the nurse who puts on those nipples. That leads to a suggestion which has not been much emphasized. Hospital nurses should be taught that medical asepsis is essentially the same as surgical asepsis, and that a clean baby is subject to infection from a previous baby, just as a clean hernia wound might be from a preceding infected appendicitis wound. The medical asepsis will be a slow way to control an existing epidemic. The closing of the nursery may be necessary in every case for promptness of result. Having done that for the prevention of another epidemic, one might try out medical asepsis. Coincident with my observation in a group of cases, I read the article by Sauer in the *Journal of Pediatrics* on "Medical Asepsis in the Cradle" in his Evanston village. And if you want to try to prevent these epidemics in the future and haven't read the article, get it. I think it was in the April or May issue of last year.

DR JOSEPH GOLOB, New York. The differences expressed in this discussion prove very definitely the difference between those who have seen this entity and those who have only read or heard about it. It is my fortune to have lived through one of the epidemics so ably described by the authors. I was struck by the fact that the victims were normal babies who suddenly and for no apparent reason become severely dehydrated. In one day they look as if they had had diarrhea for several weeks. I had the temerity to call in the Rockefeller Institute, thinking that possibly there might be some virus work done that would discover the cause. I also suspected that this widespread disease, occurring suddenly in so many towns, might be the result of an infection that had been brought from the Chicago fair, which might have been a cause infecting the mothers. In all cases there was nothing found either by the health department or by the Rockefeller Institute. It ran like other epidemics in one respect, starting mildly, rising to a peak and then subsiding. The first cases, at autopsy, showed absolutely nothing. Toward the middle of the series microscopic blood was obtained, and at the very last, macroscopic blood was sometimes found in the intestine. Those of us who have seen these cases in any number feel definitely that this is a distinct and separate disease entity and is not in any way related to the types that have been described in the literature heretofore. If the authors have impressed this section with the fact that this condition is a disease entity, and that it needs a lot of careful study, I feel that their excellent talk has been a very valuable contribution.

DR JOHN L. RICE, New York. In closing I want to emphasize this fact. Here, apparently, is a situation to which we would like to get the rest of the country sensitized, to study it, and to go more carefully into the whole problem. The conclusions that we have drawn may be quite indefinite, but we think they deserve careful study, because in cities with large populations it is a real and important problem at the present time.

Should Be Subsidized Rather Than Taxed—The spirit of investigation—all too rare—should be generously subsidized rather than taxed, encouraged rather than hindered. An isolated set of experiments by one participant in that congress of 1881 is said to have saved enough for France to enable her to pay the heavy indemnity which the outcome of a war had imposed upon her. Nature is loath to give up her secrets, discoveries do not come by chance—they are made by those only who are industriously prepared to observe them, and the inquisitorial methods of those who seek the light through experimentation, misjudged as cruel, are necessarily stern and persistent, whether the investigator deals with inanimate objects or with animate beings—Cushing, Harvey. *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co, 1928.

STUDIES ON TETANUS TOXOID

II ACTIVE IMMUNIZATION OF NORMAL PERSONS WITH TETANUS TOXOID, ALUM PRE- CIPITATED, REFINED

HERMAN GOLD, M.D.

CHESTER, PA.

Thirty-four adults were actively immunized against tetanus. Treatment consisted of two injections of tetanus toxoid, alum precipitated, refined, no 5969-1, given to all but one subject, ninety-two days apart. Patient 34 received the second dose 122 days after the first injection. Sixteen members of the group were given 0.5 cc of the alum toxoid at each injection, while the rest received a 1 cc dose.

The alum precipitated toxoid used in this study was prepared at the Mulford Biological Laboratories, from a lot of tetanus toxin that contained over 20,000 minimal lethal doses per cubic centimeter. Antigenic tests performed with this toxoid showed that the injection of 0.5 cc into standard guinea-pigs produced at the end of six weeks 5 units of tetanus antitoxin per cubic centimeter of blood serum. The injection of 1 cc of this toxoid also produced 5 units. Similar values were obtained after the injection of 5 cc of this antigen. This titer was well maintained in practically all the animals at the end of eighteen weeks.

A systemic reaction occurred in only one person, patient 34, who developed generalized pruritus and urticaria half an hour after the injection of the second dose. It lasted about one hour and was promptly controlled by epinephrine hydrochloride. Local reactions at the site of injection, consisting of moderately severe swelling, redness, pain and tenderness, occurred in almost 20 per cent of the cases, regardless of the dose used. It lasted from two to three days, and in a few of the patients there developed tender indurated nodules, similar to those seen after the injection of diphtheria toxoid, alum precipitated. These were absorbed in from three to four weeks without softening or ulceration. This locally irritating factor was eliminated from the toxoid by further refinement in its method of preparation.

The first dose of alum toxoid did not materially increase the antitoxin titer of our patients. It seemed to prepare the antibody producing cells, so that following the injection of the second dose of toxoid there occurred a rather prompt and marked increase in the antitoxin content of the blood.

Table 1 shows the results obtained in the group that received two 0.5 cc doses of toxoid. Of six patients tested seven days after the second dose, only one showed —0.1 unit per cubic centimeter of blood serum. When tested eight days later, this patient's titer had increased to +0.25 unit. The rest showed 0.25 unit or more per cubic centimeter of blood serum. Of ten patients tested fifteen days after the second dose, all showed 0.1 unit or more. Actually, one patient showed 2 units, one had 3 units and two had +1 but —5 units.

Fourteen patients were retested, ninety-one days after the second dose of toxoid. Of these, six showed —0.1 unit. The rest showed 0.1 unit or more. A

decided drop in antitoxin titer had occurred. Two subjects were tested 122 days after the second dose. One of them showed —0.1 unit, while the other had +0.1 but —0.25 unit.

Bleeding was done in the entire group and the serums were tested 181 days after the second dose. Of the sixteen subjects tested, only four showed +0.1 unit. One of them actually had +0.5 unit but —1 unit. The other twelve subjects showed —0.1 unit.

Table 2 shows the results obtained in the group that received two 1 cc doses of toxoid. Of eight subjects tested seven days after the second injection, only one showed —0.1 unit. A second patient showed 0.1 unit. The rest had +0.25 unit. Of nine patients tested fifteen days after the second dose, one showed 0.25 unit, while the rest had +0.25 unit. Among the latter, one subject showed 2 units, one had +1 but —3 units, and 1 showed +3 but —5 units. One subject tested thirty-one days after the second dose showed 5 units.

Of seventeen patients tested ninety-one days after the second dose of toxoid, only two showed —0.1 unit. Another subject had 0.1 unit, while the rest showed 0.25 unit or more. One patient tested 153 days after the second dose showed 0.1 unit.

Fifteen subjects were retested 181 days after the second dose. Of these, eight showed —0.1 unit. Four had 0.1 unit, one had +0.1 but —0.25, one had 0.25 unit, and one showed 0.5 unit. One patient when tested 212 days after the second dose showed +0.10 but —0.25 unit.

COMMENT

Although the actual antitoxin content of the blood serum was determined in many members of this group, I was primarily concerned in testing for 0.1 unit and 0.25 unit, since I felt that active immunization against tetanus, to be of value, must produce an antitoxin titer at least equal to that present in the blood following passive immunization with 1,500 units of tetanus antitoxin.¹

I have determined the duration of the active immunity produced by alum precipitated toxoid in terms of this minimal protective value of 0.1 unit. It may be possible that this value is too high, that is, lesser amounts of antitoxin may be necessary to protect an actively immunized individual against infection with tetanus bacilli, but until human experimental data are produced bearing directly on this point, I feel that it is safer to err on the side of conservatism, especially since one is dealing with such a dangerous disease as tetanus.

In contrast to the previous finding in a small series of cases,¹ it is found in this study that the administration of two 1 cc doses of tetanus toxoid seemed to produce a better and more lasting antitoxin titer than that produced by the injection of two 0.5 cc doses. Thus, ninety-one days after the second dose only 11.7 per cent of the 1 cc group dropped below the minimal protective value of 0.1 unit, while in the 0.5 cc group 42.8 per cent of the cases dropped below this value. At the end of 181 days 53.3 per cent of the 1 cc group showed —0.1 unit, while 75 per cent of the 0.5 cc group dropped below this value. However, individual variation in antitoxin response after stimulation by means of tetanus toxoid is so marked that a large series of cases should be studied before a final conclusion can be reached on the effect exerted by variation in dosage on antitoxin production.

This series of cases confirms the previous observation concerning the rapid loss of tetanus antitoxin from the blood of actively immunized individuals. Six months after the second dose was administered, 64.5 per cent of the subjects showed —0.1 unit. This loss, which is more pronounced during the first three months after the second dose of toxoid, varies markedly in different subjects. This individual variation in the absence of a simple skin test to determine the antitoxin titer of a subject at any given time makes it necessary to administer a dose of toxoid every time an injury occurs. In accordance with observations to be published elsewhere, this reinjection of toxoid will serve to bring up the antitoxin titer to or above the minimal protective level. However, further studies are necessary to determine the duration of the time interval that elapses between the injection of the toxoid and the resulting increase in the antitoxin titer. If too long, tetanus infection may occur during this period unless the patient is protected by passive immunization.

Naturally, the question arises as to whether repeated administrations of toxoid will not give rise to unpleasant sensitization phenomena. Although refined, this antigen

¹ Gold, Herman. Studies on Tetanus Toxoid. *J. Allergy* 8: 230 (March) 1937.

still contains some beef broth in which B tetani is grown

From these studies it would appear that active immunization with tetanus toxoid, alum precipitated, refined, may be of value in military practice and in some phases of civil life. It would prevent the occurrence of what is clinically called chronic tetanus,² that is, cases of lockjaw with an incubation period of more than ten days. In these cases the onset of the

toxemia would coincide with a rising antitoxin curve, as contrasted with the declining titer that occurs after passive immunization

CONCLUSIONS

1 Thirty-four adults were actively immunized against tetanus by means of two injections of tetanus toxoid, alum precipitated, refined, given ninety-two days apart. Sixteen members of the group received 0.5 cc of the toxoid, while the rest got a 1 cc dose at each injection.

2 Follow-up studies revealed that the 1 cc group developed a higher and more lasting antitoxin titer than the 0.5 cc group.

3 Rapid loss of antitoxin from the blood of the immunized subjects occurred, especially during the first three months following administration of the second dose of toxoid. This loss of antitoxin varied considerably in different individuals.

4 Because of this marked variation in individual response and the lack of an easily performed test to determine immunity against tetanus, repeated injection of toxoid should be resorted to on the occurrence of an injury. Otherwise a false sense of security may result.

5 The time required to raise the antitoxin titer to a protective level following reinjection of toxoid in an actively immunized person deserves careful study.

314 East Broad Street

ABSTRACT OF DISCUSSION

Dr. Louis Tuff, Philadelphia. The employment of a prophylactic dose of tetanus antitoxin has been our principal mainstay in preventing tetanus following exposure to this infection. The immunity which this injection confers, however, is temporary in character and disappears often within thirty days. In persons who are frequently exposed to tetanus, as in military service, in certain phases of civil practice, or in certain laboratory workers, the repeated injection of tetanus antitoxin is not always feasible, chiefly because of the dangers of a possible severe serum reaction due to sensitization to the contained horse serum. This is likewise true of allergic children especially those highly sensitive to horse serum. Even though it is possible to use a bovine tetanus antitoxin, there is always the likelihood that proper precautions will not be taken in its administration, and that a severe or even dangerous serum reaction may ensue. It is in these groups of individuals that active immunization with tetanus toxoid is desirable. Such immunization seemed possible of achievement by the use of a modified tetanus toxin or toxoid, a preparation very similar to its close relative diphtheria toxoid. The clinical reports following the use of tetanus toxoid seemed at first to justify this hope and led to its endorsement as a rather certain means of protection against tetanus particularly by those interested in the sale of these products. Since the experiments reported by Dr. Gold indicate a marked individual variation in the antitoxin loss from the blood after toxoid injection it emphasizes the necessity for caution in depending entirely on previous active immunization alone. An additional injection of tetanus toxoid at the time of injury or after exposure, as suggested by Dr. Gold, may bring up the antitoxin titer sufficiently high to protect the patient against tetanus, although this can be determined only by further clinical experience. It is possible that persons who have been actively immunized may have adequate protection in spite of a low antitoxin titer, just as persons immunized actively against typhoid may show no agglutinins in their blood and yet be adequately protected. Tissue cells that are immunized actively are very responsive to subsequent injections of the antigen. This possibly explains the quick antibody response to injections given at the time of injury and may account for the difference between the antibody titer occurring after active immunization and that which occurs after passive immunization. Although sensitization to the beef protein present in the toxoid is possible, the latter is present in such small amounts and sensitization to this particular protein occurs so infrequently, that it should not interfere seriously with the subsequent reinjection of tetanus toxoid.

Dr. L. D. Bristol, New York. One of the most encouraging features of Dr. Gold's presentation is that he is a practicing physician carrying on active research. I think we should encourage that as much as possible. Many of us doing full time work in the fields of preventive and industrial medicine and having opportunity for carrying on research may be expected to be presenting articles of this sort, but when a practicing doctor presents the results of his research it is most heartening.

² A. C. Hurst, A. P. C. Surgery—Its Principles and Practice, ed. 3 Philadelphia: Lea & Febiger, 1927, p. 87.

DR HERMAN GOLD, Chester, Pa. In spite of the claims made by a number of biological houses sponsoring and marketing tetanus toxoid, the story of active immunization against tetanus is as yet not completely known. Since it is still in the experimental stage, we ought to be cautious in its use, otherwise we may run into cases of lockjaw in persons thought to be actively immunized. I feel that it will be useful in certain types of medical practice, but I fear that it will not, from my present experience, be suitable for the general use which is being advocated for it at the present time.

THE ISOLATION OF TETANUS BACILLI FROM STREET DUST

ITS BEARING ON SURGICAL PRACTICE

ERIC C. GILLES, L.R.C.P. & S., Dr. P.H., D.Sc.
BALTIMORE

In reviewing the extensive literature on tetanus, the reader will have forcibly brought home to him the absence of much specific work on the isolation of tetanus bacilli from street dust. As far as could be ascertained, practically no worker has concentrated on this particular phase of the distribution of tetanus spores except Nicolaier¹ in 1884 and Bossano² in 1889, who examined samples of both street dust and soil for the presence of tetanus spores. Their method, however, consisted of the injection of mixed material or impure liquid cultures into laboratory animals. Subsequent workers have taken for granted the existence of spores of tetanus in street dust, as is evidenced by the repeated statements to this effect in the literature in general. So deep rooted is the idea that tetanus spores exist in street dust that, apart from the use of tetanus antitoxin both as a prophylactic and as a curative measure in all cases of war wounds, it is a universal practice to give as a routine on admission to hospital an injection of tetanus antitoxin in all cases of street accidents, however slight the injury may be, provided there is any laceration or abrasion of the surface skin.

Its value as a prophylactic is established, and the theory is generally accepted that tetanus bacilli regularly inhabit the intestinal canal of man and of animals, which is the main source of environmental replenishment of these organisms. There are still some practitioners, however, who firmly believe that with the fast disappearance from the busy thoroughfares of large cities of horse-drawn vehicles, which now survive only in the small numbers used by bread and milk vendors, the chances of infection from street dust following accident are practically negligible. Moreover, the replacement of old cobbled streets with smooth asphalt and easily cleaned tarmac is considered to have removed conditions favorable for the accumulation of decomposing protein material, in which the tetanus bacilli are known to thrive. They therefore question the value of the administration of a prophylactic injection of antitoxin in cases of street accidents. In fact they maintain that a greater danger exists of producing an anaphylactic phenomenon in persons susceptible to the injection of a foreign serum, with perhaps disastrous results, than in failure to give a prophylactic injection of antitoxin in cases of street accidents in which there are open wounds.

It appears impossible to refute this statement without additional systematic study, as, for instance, by the isolation of tetanus organisms from street dust in a large city. The results of such an investigation would certainly be of practical value and throw much light on the important question: Is prophylactic treatment with tetanus antitoxin essential in the case of all persons injured in street accidents?

I undertook such an investigation in Baltimore and in this paper present briefly the method employed and the results of my study to discover the presence in and to isolate tetanus bacilli from samples of street dust. The samples were gathered at random from a region some 9 square miles in extent in downtown Baltimore bounded by North Avenue, Patterson Park Avenue, Pratt Street and Pennsylvania and Fremont avenues, comprising both residential and commercial areas, as shown in the accompanying illustration.

The samples were collected from the edges of street pavements removed as far as possible from recent contamination with horse manure and were put into cardboard boxes which had been previously sterilized by dry heat at 170 C for two hours.

The collected samples of dust brought to the laboratory were then stored in the cold room until their

Section of Baltimore from which samples of dust were collected. The plain dots show the source of material from which no tetanus bacilli were isolated; the encircled dots the source of material from which toxic strains of tetanus bacilli were isolated; and the encircled crosses the source of material from which nontoxic strains of tetanus bacilli were isolated. (From a photograph by F. Paul Feder.)

examination, precautions being taken to avoid mixture or contamination during the period of storage, and before the containers were opened the exterior was flamed.

TECHNIC EMPLOYED

About 10 to 20 Gm of dust from each sample was weighed on sterile filter paper and put into flasks containing about 40 to 45 cc of sterile saline solution. The flasks were then heated four at a time in a water bath to a temperature of 80 to 82 C for one hour. After this preliminary procedure, adopted to eliminate nonsporing contaminating organisms, the flasks were shaken, and the suspensions of dust, containing only the spores of aerobes and anaerobes, were poured into other flasks containing about 95 cc of Bengtson's cooked meat medium, which prior to inoculation were heated for fifteen minutes at 100 C and rapidly cooled. After the dust suspension was thoroughly mixed in this medium, the surface of each culture flask was covered with melted petrolatum to a height of about 1 cc to maintain anaerobiosis, and the flask was then incubated for a period of from eight to ten days at 37 C for the germination of any spores of tetanus that might be present.

The appearance of the culture flasks after three or four days' incubation was characteristic. In practically every flask the petrolatum caps had been pushed up to

The investigation was carried out in the Department of Bacteriology of the School of Hygiene and Public Health of the Johns Hopkins University, under the direction of Dr. W. W. Ford, professor of bacteriology, on a scholarship awarded by the faculty of the school.

¹ Nicolaier, A. *Deutsche med. Wochenschr.* 10: 842, 1884.
² Bossano, P. B. *Rev. de med.* 9: 102, 1889.

the neck, the entire medium was blackened, the meat particles had been almost completely digested and the odor was most offensive

The problem that now presented itself was the separation of the spore-bearing aerobes from the spore-bearing anaerobic bacteria in the mixed cultures. Various methods were tried in an endeavor to stimulate the growth of the anaerobes but at the same time to inhibit the multiplication of the aerobes. The method of employing dyes as recommended by Hall³ was found most suitable and satisfactory for this investigation.

This method consisted of repeated transfers of cultures in dextrose broth containing a selective dye in a particular dilution. Crystal violet, the chemical name of which is hexamethylrosaniline chloride and which has the formula

was used in this work in a dilution of 1 in 100,000, as follows

About 5 cc of the material from each of the original mixed cultures grown for ten days in Bengtson's meat medium was drawn out with a sterile pipet, transferred to sterile tubes and heated in the water bath at 80 C for fifteen minutes. Two cubic centimeters of this heated material was inoculated into dextrose broth dye tubes previously heated to 100 C, cooled and layered with a cap of petrolatum. The inoculated tubes were then incubated for eighteen hours at 37 C, at the end of which time the tubes usually showed marked turbidity, with a large amount of gas production. In many of the tubes the medium was decolorized.

Transfers were then made from the dextrose broth dye tubes with sterile pipets to agar slants, crystal violet dextrose broth and Holman's meat tubes. The agar slant tube was incubated aerobically and served as a test for the presence of aerobes. The crystal violet dextrose broth tube provided for repetition of the procedure in case the agar slants showed aerobic contamination, and the meat tubes provided a viable culture in the event the aerobes were successfully eliminated. The crystal violet dextrose broth and Holman's meat tubes were incubated anaerobically. Subculturing into dextrose broth crystal violet, agar slants and meat tubes was repeated if necessary until the agar slant from one of the series of the subcultures showed no aerobic growth after forty-eight hours of incubation at 37 C.

In the samples examined, usually three and in a few instances four or five transfers to dextrose broth containing the dye were necessary to eliminate the aerobes. When this had been accomplished the corresponding meat tube culture was incubated for another few days and the contents were tested again for the presence of aerobes. If negative results were obtained the meat tubes were considered to be free of facultative anaerobes, whereas if the test revealed aerobic contamination the process was repeated.

All the original mixed cultures were put through the same process, and cultures of pure anaerobes were finally obtained, from which the isolation of tetanus bacilli was undertaken.

ISOLATION

The method used to isolate the tetanus bacilli from the Holman's meat culture tubes containing a mixture of anaerobes was similar to that used by Fildes⁴. The condensation water of slants of peptic blood infusion agar (Fildes influenza medium⁵), which had been previously placed in the incubator for from eight to ten hours in order that the apex of the slant might be dried, was inoculated by capillary pipets with a few drops

of the culture material from the Holman's meat tubes containing the mixture of anaerobes and grown for from seven to eight days at 37 C in the electrically heated McIntosh and Fildes anaerobic jar. After this the tubes were carefully examined for the presence at the apex of the slants of the filmlike growth typical of tetanus bacilli. In many instances a hand lens was necessary to see clearly this very fine film of growth just a little below the apex of the slant. Not every tube, however, had this characteristic growth. In many it was entirely absent, yet all the tubes showed different zones of much heavier growth, indicating the presence of other bacteria, each of which may have its own limited zone of growth in a given period.

Examination of the apex of the slant with a hand lens revealed this characteristic filmlike growth in the first series of inoculations of eight of the sixty-three samples from which tetanus bacilli were finally isolated, whereas in the four other strains isolated the growing edge of the film was not so apparent, owing possibly to insufficient drying of the apex of the medium. On subsequent subculture, however, these four strains too showed a more distinct and characteristic growth.

In an endeavor to obtain pure cultures these thin films of growth were subcultured in the condensation water of another set of tubes of the same medium and incubated as before. At the same time agar slants were inoculated and incubated aerobically for forty-eight hours to determine the presence of contaminating aerobes. This subculturing was repeated about four times, together with aerobic agar slant controls.

From the last subculture the upper film of growth was transferred to Holman's meat medium, sealed with petrolatum and incubated at 37 C for three days. Smears were then made from these cultures, stained and examined for the presence of tetanus-like organisms.

In twelve of the sixty-three samples examined tetanus-like organisms were seen, but in only two of the twelve strains did they appear in pure form after the fourth subculture. It was necessary to subculture the strains isolated five, six and in one instance seven times before pure cultures, as revealed by microscopic examination of stained smears, could be obtained.

For the final purification of the isolated strains, Veillon and Zuber's⁶ shake tube technique was employed, which involved seeding tubes of melted infusion agar cooled at 50 C with a few drops of a series of appropriate saline dilutions made with material from the meat cultures of each of these strains. The tubes were then rolled between the hands to disperse the organisms thoroughly in the medium, solidified rapidly by placing the tubes in ice cold water and incubated for three or four days at 37 C. When colonies in the shake tubes had attained a fair size, they were picked out as follows.

The closed end of the tube was heated slightly so as to melt the agar, and by gradual heating toward the mouth of the tube, which had previously been flamed, the column of agar was driven out, it was received into a sterile petri dish, the surface of which was then flamed by passing a Bunsen burner over its entirety. The column of agar was now sliced with a sterile scalpel above and below the colony desired and the colony in the agar picked up with a platinum spud, transferred to tubes of meat medium and crushed on the sides of the tubes. This was essential for the growth of the organisms.

By repetition of the shake tube procedure, pure cultures of eleven of the twelve strains isolated were obtained. One strain gave a good deal of trouble in purification, and it was necessary to repeat the shake tube method four times more before it was finally obtained in pure culture. Each strain thus isolated

was grown anaerobically in Holman's meat medium for five days at 37 C and tested for contamination by examination of stained preparations and aerobic slant controls

When the strains showed definite purity, two other sets of Holman's meat tubes were inoculated with culture material from each pure strain, layered with petrolatum and incubated for three days, and from one set of these the biologic characteristics of the strains were studied

The characters used in the identification of the twelve strains isolated in pure form in this study were morphology, staining reactions, motility and biochemical reactions

TOXICITY TEST

In any study of tetanus the toxicity test for pathogenic action forms the crux of the whole investigation,

Toxicity Tests of Strains Isolated

Sam ple Num ber	Strain Num ber	Mouse A		Mouse B		Results
		Given 0.3 Cc of Tetanus Antitoxin and 1 Hour Later 0.3 Cc of Culture Medium Intramuscularly		Given 0.3 Cc of Culture Medium Intramuscularly

and a demonstration of characteristic toxicity in cultures is necessary for absolute identification

To carry out this test, the twelve strains isolated which corresponded in morphology and cultural reaction with *Bacillus tetani* were grown in Holman's meat medium and incubated anaerobically for ten days at 37 C, after which 0.3 cc of the clear supernatant fluid drawn from each of these cultures was injected intramuscularly into the right thigh of white mice. Controls were run with white mice which had been given, an hour before receiving the same dose of culture fluid, 0.3 cc of antitoxin containing 700 units per cubic centimeter. All mice which survived four days after the injection were watched for three weeks prior to destruction for the development of symptoms

The results of the toxicity tests are given in the table. It will be observed that three of the strains were nontoxic. Nine strains yielded a spasm-producing toxin which was fatal to white mice and was neutralized by a protective dose of antitoxin, the protected animals surviving three weeks after receiving the injection. Culture fluids from three of the strains had no demonstrable toxic effect on the animals given injections even after ten days. One of the three nontoxic strains, No 7, while it exhibited the morphology of tetanus bacilli, differed in its biochemical reactions in failing to liquefy gelatin and in producing acid and gas in dextrose and in maltose. It was regarded as a strain

of *Clostridium pseudotetani*. The other two strains, Nos 2 and 9, had a morphology like that of tetanus bacilli and in addition gave similar biochemical reactions. In view of the observation of nontoxic strains by other workers, namely, Vaillard and Vincent,⁷ Adamson,⁸ Heller,⁹ Fildes⁴ and Bauer and Meyer,¹⁰ it may be concluded that these two strains are nontoxic strains of tetanus bacilli, in all probability variants from toxic strains.

SUMMARY AND CONCLUSIONS

This investigation was undertaken to determine the presence of tetanus spores in street dust. The method employed was to cultivate the material, isolate tetanus-like organisms, study their biochemical reactions and, finally, demonstrate the ability of the strains isolated to yield a spasm-producing toxin which could be neutralized by tetanus antitoxin.

As a preliminary to the isolation of pure cultures, it was necessary to grow the mixed material in special mediums to stimulate the growth of any tetanus organisms present and then to eliminate the vegetative forms of bacteria by heating the material at 80 C for twenty minutes. Since, however, the spores of sporulating aerobes and facultative anaerobes were present, the use of selective dyes in the medium was found necessary to eliminate them. The dye employed was crystal violet, which was found to be entirely satisfactory. In the separation of the tetanus organism from other spore-bearing anaerobes, the method originally employed by Fildes⁴ was used. This procedure makes possible the isolation of tetanus organisms from a mixture of anaerobes.

The biochemical reactions of the strains of *Clostridium tetani* isolated were studied, and their toxin-producing ability was demonstrated by the inoculation of animals. From the sixty-three samples of street dust obtained from various streets within a limited area of Baltimore and examined in this investigation, eleven strains of tetanus bacilli were isolated, that is, 17.4 per cent of the samples revealed the presence of the organism. Of these, nine strains, or 14.2 per cent of the samples, yielded a spasm-producing toxin neutralized by tetanus antitoxin, whereas two strains isolated from 3.17 per cent of the samples did not yield any detectable toxin.

The results obtained in this investigation do not permit of comparison with any other work of a similar nature, since apart from the early observations of Nicolaier¹ and Bossano² no reports have been found in the literature of the isolation of tetanus organisms from street dust, and the present investigation appears to be the first successful isolation of tetanus bacilli from the street dust of a large modern city of the United States.

The positive results are definite and conclusive proof that *Clostridium tetani* is widely distributed in street dust even at the present day and establish the absolute necessity for the use of prophylactic injection of tetanus antitoxin in all cases of street accidents accompanied by laceration or abrasion of the cutaneous surface. The fear of anaphylaxis can no longer justify the failure to employ protective serum in every case of street accident in which there are open wounds, since street dust, contrary to the views of many, has been shown to be a potential source of danger.

MUNICIPAL CONTROL OF WHOOPING
COUGH

LOUIS SAUER, M.D.

EVANSTON ILL.

In 1934, soon after the paper entitled "Immunization with *Bacillus Pertussis* Vaccine" was published in *THE JOURNAL*,¹ Dr. John W. H. Pollard, Evanston² Commissioner of Health, opened a municipal whooping cough prophylactic vaccination clinic at the "Health Center." Diphtheria had been rendered an infrequent disease, 133 cases with ten deaths in ten years. Whooping cough was twenty-five times more prevalent, 3,338 cases with five deaths. Because immunization with diphtheria toxoid had been reported less permanent when given in very early life, and as most deaths from pertussis occur during infancy, pertussis vaccination is given before diphtheria toxoid—preferably between seven and ten months. At least several months intervene between pertussis vaccination and any other immunization procedure. To determine whether the customary total dosage of 8 cc of authorized commercial vaccine is sufficient to protect children more than 2 years old, fifty "Welfare" children between 2 and 4 years of age were included. The nurses, during the Infant Welfare conferences, or at house visits, tell the mothers of infants in the designated age range about the three weekly injections. The mother signs a consent card. The two hour clinic is held on six consecutive Wednesday afternoons. Usually about fifty new candidates are injected at each of the first four weekly conferences, so that 200 or more vaccinations are completed in six weeks. In the spring clinic the one, in the autumn clinic the other, brand of vaccine authorized by Northwestern University Medical School is used. Syringes and needles are sterilized by heat, the injection site (upper arm) is sterilized with alcohol. The physician in charge injects the vaccine just under the skin. Mothers are cautioned not to apply anything locally, if a transient redness appears. No severe reaction or infection has occurred. On the day of the third

injection, record cards are filed in triplicate, and the mother is given a pertussis vaccination certificate.

The number of Evanston children injected annually since 1934 by private physicians and at the municipal Health Center is summarized in table 1. With improvement in the economic status during the last few years

the annual number privately injected has increased, whereas the number of municipal injections has correspondingly decreased. At seven semiannual clinics, 1,122 Evanston "Welfare" children completed the pertussis prophylactic vaccinations, seven children failed to complete the series, owing to prolonged intercurrent illness or to removal from the city. The average age of the clinic children is about 10 months, that of the privately injected children is probably somewhat more. Prior to June 1, 1937, at least 2,769 Evanston children have completed the prophylactic injections.

Table 2 is a three year summary of Evanston's municipal whooping cough prophylactic vaccination clinic. The nurses of the various agencies—the Infant

Welfare, communicable disease control, school and visiting nurses—in close daily contact with the contagious disease situations reported to the department of health—128 children who were presumably exposed to whooping cough after they had been injected. Ninety-four were exposed to clinical pertussis in their own households, i. e., brothers or sisters developed the disease after the younger child had been vaccinated, thirty-four were casually exposed to pertussis while at play or in the classroom. In the three years, six injected children developed whooping cough. All six failures occurred in children who were vaccinated in the autumn of 1934. A child injected after intimate exposure developed clinical pertussis before the injections were completed.

The six clinic children who developed whooping cough after vaccination are listed in table 3. Relatively few (about fifty) of the clinic children were more than 2 years of age when they were injected, less than 5 per cent of the total number injected.

Because five of the six who developed pertussis were more than 2 years old when they were injected, the total dosage for children of more than 2 or 3 years was increased in 1936 to 10 cc. The initial dose remains unchanged (2 cc), but the second and third doses are increased (from 3 cc to 4 cc) if the child is more than 2 years old at the time of injection. For children younger than 2 years the total dosage is 8 cc (2, 3, 3 cc at weekly intervals).

The course of the disease in five of these children was mild, it was quite severe in one. Because untreated whooping cough varies in severity and duration—light cases outnumber the severe—proper evaluation of any therapeutic measure is difficult. The psychologic effect (on child, parent, nurse and physician) of hypodermic therapy increases the dilemma. Infants and delicate young children with pertussis during cold weather are kept warm and isolated, preferably in bed, for several weeks. The air is kept fresh, warm and moist, drafts are avoided. With an aseptic nursery technique, complicating infections, as the common cold, grip and enteritis, seem to occur less frequently. The early intramuscular injection of 50 cc of convalescent blood, or the blood of an immune parent who has had three injections of the vaccine at two or three day intervals, might be beneficial to very young pertussis patients.

From the Evanston Hospital of Northwestern University Medical School.

Read before the Section on Pediatrics at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1937.

¹ Sauer, Louis. Immunization with *Bacillus Pertussis* Vaccine. *J. A. M. A.* 101: 1449 (Nov. 4) 1933.

² This city of 70,000 is an integral part of the Chicago metropolitan area. About 15 per cent of the young white children and most of the young children of the (12 per cent) colored population attend the Infant Welfare Society diphtheria and smallpox immunization clinics. In 1931 the National Health Conservation Contest First Place award for cities of this size was conferred on Evanston—an honor bestowed but once yearly since then. The Honorable Mention award has been given to Evanston. In 1936 Evanston received the national Meritorious Achievement health award.

The number of pertussis patients quarantined in Evanston each year since 1930 is shown in table 4. The number of "Welfare" children with the disease is indicated. The annual average number of city cases for the four years preceding the clinic is 325, for the three clinic years it is 290. The annual average number of "Welfare" infants quarantined with whooping cough before the vaccination clinic is forty-nine, for the clinic years it is fourteen. In 1934, when the Evanston total

TABLE 3—*Developed Whooping Cough After Vaccination*
(1934 to June 1, 1937)

Age	Vaccination Date	Diagnosis Date	Interval
1 9 mo	Oct 1934	July 1935	9 mo
2 2½ yr	Oct 1934	March 1935	5 mo
3 3 yr	Oct 1934	Feb 1935	4 mo

5 4 yr	Nov 1934	Feb 1935	3 mo
6 4½ yr	Oct 1934	March 1935	5 mo

was 181 cases, there were twenty "Welfare" cases. In 1935, when the Evanston total reached 602, there were twenty-four "Welfare" cases. In 1936, when the Evanston total was ninety-one, the lowest in the history of the department of health, only one "Welfare" child contracted pertussis.

In the 1936 Annual Report of the Department of Health, Dr Pollard said:

For the last decade, the average yearly total of whooping cough patients reported was 334. In 1935, 602 cases were quarantined. For the year 1936, the incidence of this disease dropped to ninety-one cases. Investigation developed the fact that ninety of these cases had never been inoculated against whooping cough. The ninety-first case developed whooping cough, through previous exposure, during the period of inoculation. All children treated at these clinics are referred by local social agencies, who vouch for the financial status of the families concerned.

CONCLUSIONS

At the Evanston Municipal Pertussis Prophylactic Vaccination Clinic, a total of 1,122 "Welfare" children have been injected since 1934. The best age for the injection of a total dosage of 8 cc (2, 3, 3 cc at weekly intervals) of authorized vaccine is probably the second

half year of life, preferably between the seventh and the tenth month. Five of the six "Welfare" children who developed pertussis after vaccination were more than 2 years old when injected. Children over 2 years of age probably require a total dosage of 10 cc (2, 4, 4 cc at weekly intervals).

636 Church Street

ABSTRACT OF DISCUSSION

DR LEROY D FOTHERGILL, Boston. Dr Sauer has presented a summary of his experiences with the prevention of whooping cough in Evanston Ill. In 1931 Leslie and Gardner published their description of the dissociation of *Haemophilus pertussis*. This important contribution was the beginning of our modern knowledge of the biology of this organism. The

importance of bacterial dissociation, the antigenic structure of the different variants of a given organism in relation to virulence and the necessity for using a "whole" or "complete" antigen for the production of active immunity is a major contribution of recent bacteriologic investigations. Dr Sauer published his first report on the prophylaxis of whooping cough soon after Leslie and Gardner's description of the dissociation of *Haemophilus pertussis*. He is to be given great credit for the practical application of this bacteriologic knowledge in studying anew the prevention of pertussis. Dr Kendrick and her associates in Grand Rapids have published several reports which confirm, in the main, the results obtained by Dr Sauer. On the other hand, Doull and his co-workers failed to confirm these experiences. Because of the variable nature of pertussis and the uncertainty of exposure it is extremely difficult to make an adequately controlled epidemiologic study of the prophylaxis of this disease sufficient to satisfy the most skeptical. This, however, should not prevent the accumulation of such data as will ultimately provide an answer satisfactory to all. Our knowledge of the immunology of this disease is extremely meager. By what mechanism is the solid and, with rare exceptions, permanent immunity following the natural disease maintained? There is no evidence, at present, of any circulating antibody sufficient to account for it. If such a circulating antibody were present it might protect new-born infants through passive transplacental transfer from the mother, as in diphtheria. The infant, however, is susceptible to pertussis. This question might well be pondered by those who advocate the use of convalescent serum in the treatment or prophylaxis of pertussis. Furthermore, if the immunity were due solely to a circulating antibody could such an antibody get into the locus of pathology in an adequate concentration? Consider the barriers to such transport. Is the immunity following the natural disease largely a cellular phenomenon? If so, is it local or generalized? It is quite possible that the various opsonocytophagocytic studies being conducted at the present time may give information on this point. I have not raised these questions in a spirit of doubt but rather to suggest lines of thought which might profitably be pursued in the future. Are the two dependent on the same immunologic mechanisms?

DR CHARLES GILMORE KERLEY, New York. Not having an opportunity to make a municipal study of whooping cough and knowing something of the work that is being carried on in New York City, I appealed to Dr Muckenfuss, who had charge of a study of whooping cough immunization in New York City. Dr Muckenfuss writes me as follows: "About two years ago a study was initiated at the Prospect Clinic in Brooklyn. Children under 5 having a negative history of whooping cough were selected and alternate cases were vaccinated making an effort to secure controls in the same family. 1,276 children were vaccinated and 1,026 served as controls. These children were visited once a month and when any illness occurred, a physician visited them. Several vaccines have been used, Sauer's vaccine prepared by a commercial firm and the vaccine distributed by the Department of Health. About half of the children received a dose of 80 billion as recommended by Sauer and the remainder received smaller doses. At present the gross incidence among the vaccinated children is 35 per cent and among the controls 41 per cent. The incidence in those receiving a small dose is 52 per cent and those receiving a large dose 165 per cent. The size of the experiment is obviously inadequate and it is impossible to draw conclusions on the lower incidence among those receiving a large dose because of the higher incidence among those receiving a small dose as compared to the controls." In evaluating the virility of immunizing agencies, one must consider the possibility of the natural immunity possessed by the patient and the virulence of the prevailing epidemic. The present is a period characterized by the absence of severity of diseases of the contagious type, standing out in marked contrast to the late nineties and early nineteen hundreds. I refer particularly to measles, mumps, scarlet fever and whooping cough. Further, I would call attention to the superiority of the child of the present day in comparison with the period referred to. He is a better type individual with a higher health standard, perhaps a greater resistance to infection and capacity for protection in case of illness.

D BEN MARTINEZ, MD
PITTSBURGH

The problem of a safe and sane method for the resuscitation of the new-born requires serious thought at the present time, owing to the fact that each day more women demand the use of various drugs to make "childbirth painless," with the natural sequela that the obstetrician has to deal with more narcotized babies. This demand, as the obstetrician knows, is due to the unfortunate publicity given in the lay press about their uses. Although the information emanates from medical sources, the doctors as well as the laity have nerve enough to criticize the high maternal and fetal mortality in which these drugs play a part.

The staff at Magee Hospital has gone through the various stages in the development of resuscitation of the new-born, i.e., the old mouth to mouth method, the hot and cold tubing, various forms of the manual methods, and the use of oxygen or oxygen-carbon dioxide mixtures held over the baby's face by means of a funnel or a catheter placed down in the baby's larynx for it to receive the gas in a concentrated form.

In 1930 I imported a von Wachenfeldt respirator from Sweden. This chamber type of apparatus, in which a definite (15 mm) positive and negative pressure is exerted on the baby's body with the head remaining outside the cabinet so that oxygen can be given directly to the fetus, seemed to us to be an improvement over previous methods.

However, since July 20, 1934, we have been using the E & J Resuscitator. It is a positive and negative apparatus, and the pressure is exerted by the oxygen over the baby's face through a mask similar to that used in administering gas anesthesia. The apparatus

The reversal of positive pressure to negative pressure and vice versa is brought about by a tripping mechanism which operates when the intrapulmonary pressure of the patient's lungs reaches either the predetermined positive or negative pressure. This principle of operation enables the apparatus to adjust itself automatically to the proper volume and respiratory rate of any size lung regardless of how small or how large. A very rapid tripping, due to the diminished capacity, warns the operator when the airway is obstructed by mucus, the tongue or some foreign substance.

TABLE 1—Data Compiled from Resuscitation Charts

A	Mechanical resuscitation used	
	From a few seconds to 5 minutes	252 times
	From 5 minutes to 15 minutes	144 times
	Over 15 minutes	104 times
B	Degree of asphyxia	
	Mild	248
	Moderate	188
	Severe	64
C	Type of asphyxia	
	Livida	372
	Pallida	128
D	Cause of asphyxia	
	Narcotized	124
	Cerebral injury	68
	All other causes	308*
E	Type of delivery	
	1 Spontaneous	100
	2 Breech extraction and internal podalic version and extraction	184
	3 Forceps	148
	4 Cesarean section	68
F	Indication for resuscitation	
	1 Infants that would have lived without resuscitation but in whom it was used because it was thought to benefit the new born	315
	2 Infants that would have died without resuscitation of some sort	138
	3 Infants that we believe would have died if any other apparatus that we had before this one had been used	24

* The largest number of cases occurred in this group because we were unable to find the cause of the asphyxia or it was due to some congenital deformity such as hydrocephalus.

When spontaneous respiration has been established, the respiratory efforts of the patient cause the sensitive mechanism to respond by tripping rapidly or irregularly. At this stage the operator turns a lever and the apparatus is immediately changed from a mechanical resuscitator to a simple inhalator. During the inhalation treatment the patient breathes through his own efforts from a bag which supplies either pure oxygen or a mixture of oxygen and air, whichever is indicated.

The various safety features of the machine make it impossible to supply a pressure of more than 19 mm of mercury in the patient's lungs.

After his work with Kreiselman on the carbon dioxide content of the blood in the new-born, Kane¹ reported that pure oxygen seemed to be entirely satisfactory as a resuscitating agent. After reviewing these articles we used pure oxygen until after respiration was well established in this series about to be reported. Then, occasionally, we used the oxygen-carbon dioxide mixture but felt that there was little or no advantage over the straight oxygen.

There is a very important point that is universally known in the resuscitating of the new-born, but it should be emphasized again: it is of the utmost importance that the mucus be removed from the respiratory apparatus of the baby before any form or type of resuscitation is started. If this is not done, the baby will inspire the mucus down into the lungs, or the respirator may force the material into the lungs, and every one knows what the results would be.

Physician

is equipped with two tanks—one of oxygen and the other a mixture of 90 per cent oxygen and 10 per cent carbon dioxide, so that either can be used with ease.

The mechanism of the E & J Resuscitator is contained in a central cylinder and is mounted on a three wheel carriage. The motivating power is derived from the pressure in the oxygen tanks. The apparatus exerts a positive pressure of 13 mm of mercury and a negative pressure of 9.75 mm of mercury in a continual alternating sequence.

We now have a series of 500 cases, which includes all the cases that occurred in all the obstetric services of the Magee Hospital in which the E & J Resuscitator was used. Records for the necessary information relative to these cases were made on a chart, which is a form that was submitted to the American Medical Association and approved by it.

From this chart we were able to compute the data in table 1.

TABLE 2—Cause of Death in Cases Which Did Not Come to Autopsy

Intracranial hemorrhage	8
Prematurity	6
Atelectasis	2
Cause unknown	9
Tumor of abdomen and bilateral clubfoot	1
Malformation of abdomen	1
Placental abruption heart tones heard for 2 minutes after birth	1
Toxemia in mother heart tones heard for 1 minute after birth	1
Syphilis	1
Hydrocephalus	1

In group F 1, we used the apparatus more often than necessary. Now, as soon as a baby is born and does not cry immediately, we simply aspirate the mucus and apply the resuscitator, believing that we may be saving some of the babies from an asphyxia that may become more serious. We believe that it is important to supply oxygen to the tissues of the baby's body as soon as possible, and for that reason too we like to use the inhalator.

In group F 2, quite a few of the babies were saved, but it would be difficult to say what number.

In group F 3, judging from our past experience, we believe, at least in our hands, that twenty-four is a conservative number.

TABLE 3—Autopsy Reports on Infants Treated in the Respirator

Baby B (A 48 34)—Defective interventricular septum with generalized anasarca
Baby McC (A 61 34)—Diaphragmatic hernia congenital abscess of left diaphragm
Baby C (A 82 34)—Cerebral hemorrhage petechial hemorrhages in lung partial pulmonary atelectasis*
Baby S (A 86 34)—Partial pulmonary atelectasis with no hemorrhages the free borders of the lung showed some emphysema the gastro intestinal tract appeared normal
Baby A (A 5 35)—Cerebral hemorrhage fracture of the right clavicle right posterior subpleural hemorrhage partial pulmonary atelectasis
Baby H (A 47 35 stillborn)—Partial pulmonary atelectasis no hemorrhage dilated descending colon but rest of gastro intestinal tract normal in appearance
Baby P (A 48 35)—Intracranial hemorrhage partial pulmonary atelectasis with only slight aeration along the anterior borders gastro-intestinal tract normal
Baby C (A 9 36)—Intracranial hemorrhage petechial hemorrhages in lung which microscopically showed red cells in the alveoli proper in some areas the alveolar walls were markedly engorged
Baby M (A 25 36)—Intracranial hemorrhage atelectasis of both lungs

* There was no evidence of injury to the lung. The stomach was small.

In the entire series there were thirty-one deaths, and the apparatus was used on sixteen stillborn infants in the hope that we could get autopsies on them to see whether any damage had been done by the apparatus. However, we obtained only one autopsy on a stillborn baby, which will be referred to later in this paper.

The causes of the thirty-one deaths, except those in which an autopsy was done, are given in table 2.

In those cases which came to autopsy it is interesting to note that there was no damage done to the lungs, stomach or any other viscera by this apparatus. Among

the infants who died on whom autopsies were not permitted, it is interesting to note that only two died of atelectasis, which, I believe would be a larger number had proper resuscitation not been instituted.

SUMMARY

I believe that this mechanical positive and negative pressure apparatus is a definite improvement over any other method, not only in resuscitating the babies that actually need it but also in aiding the babies that just do not cry vigorously.

The safety of this apparatus is certainly an important factor, since any one (nurse or intern) with a little training can use it, thereby permitting the obstetrician to devote his full attention to the mother, when needed, as is very often the case in difficult deliveries, in which asphyxia is apt to occur.

The resuscitator is almost fool proof, as the positive and negative pressure ceases automatically when the child breathes of its own accord and allows it to breathe the oxygen from the bag, or, if desired, it may breathe the oxygen-carbon dioxide mixture through the inhalator attachment.

I believe that this is a definite life-saving device and should be a part of the armamentarium of all hospitals that have obstetric patients.

SIGNIFICANCE OF THE INCREASED FREQUENCY OF SELECTIVE CORTICAL NECROSIS OF ADRENAL

AS A CAUSE OF ADDISON'S DISEASE

H GIDEON WELLS, M D

ELEANOR M HUMPHREYS, M D

AND

EMMA G WORK, B S

CHICAGO

The increasing frequency of contacts with new chemicals, whether in industries or in therapeutics, is bringing about new disease conditions. The picture of some diseases is being modified, the frequency of other pathologic states is being made greater or less, and possibly entirely new conditions are being produced. Unfortunately the harmful effects of therapeutic agents or industrial poisons commonly are not recognized until much damage has been done. Chloroform had been widely used for half a century before the menace of toxic necrosis of the liver was generally recognized and the use of chloroform for anesthesia largely abandoned. Despite numerous early admonitions, it was not until after 1900 that chloroform necrosis was found to be a widespread and common occurrence which had usually escaped recognition because designated as something else, e g, puerperal acute yellow atrophy, when it followed delivery under chloroform.

The liver indeed is particularly susceptible to damage from toxic chemicals, and many agents besides chloroform produce the appearance of "acute yellow atrophy." During the war this condition was observed frequently as a result of absorption of chemicals used in making explosives and other war materials. In the prohibition era there was also a heightened incidence of similar conditions produced by the unbelievable consumption of

From the Department of Pathology of the University of Chicago and the Otho S A Sprague Memorial Institute.

varnish removers, hair tonics, cleaning fluids or anything thought to have intoxicating properties. Now is seen especially the hepatic effects of cinchophen, and the combination of a toxic cirrhosis with the scars of rheumatic lesions in the heart often tells the story to the pathologist even when a history of the use of cinchophen is not forthcoming. As pointed out by Wells and Bassoe,¹ the production of "acute yellow atrophy" means that some toxic agent is present which has marked capacity to kill liver cells with relatively little effect on any other vital tissue, and there seem to be many chemicals with this potentiality.

Another new disease, agranulocytosis, is now well established as depending chiefly on the action of newly introduced chemical agents that have a selective destructive effect on the granulocytic and granulocytopoietic elements. Here, as with acute toxic necrosis of the liver, many different substances seem to be able occasionally to produce the specific pathologic condition, but as cinchophen is at present the most important cause of hepatic damage, so aminopyrine seems to be the most usual cause of agranulocytosis. For example, Plum² reports that 95 per cent of the cases of agranulocytosis observed in the preceding eighteen months were due to treatment with therapeutic doses of aminopyrine immediately before the onset of the disease and that the curve of incidence of agranulocytosis in Denmark during the past ten years coincides with the increase in the use of aminopyrine. Other chemicals, however, may produce the same effect, for example, gold salts, such as sanocrysin, used in tuberculosis therapy. In reporting what seems to be the first case in American literature, Schwartz and Heise³ comment on the greater frequency of such cases observed by the British, the Germans, and especially the French, who use the gold treatment so much more than American phthisiotherapists. Brailion⁴ in France states that gold treatment gives an incidence of agranulocytosis of about 0.1 per cent, with a mortality of around 50 per cent.

One reason why these serious diseases occur is that animal experiments and preliminary therapeutic trials do not disclose the danger, and in clinical trials the danger is not recognized because the full fledged pathologic condition develops in only a small proportion of those taking the drugs. Vast numbers of persons take cinchophen and aminopyrine without suffering recognizable ill effects, while on the other hand fatal results have followed the taking of but a few therapeutic doses by the rare, susceptible person. Cinchophen will not produce severe liver damage in any reasonable number of laboratory animals any more than it does apparently in at least 999 out of a thousand arthritic patients, and hence no amount of laboratory testing would indicate that cinchophen is so dangerous to man that Palmer and Woodall⁵ could raise the question "Cinchophen—is there a safe method of administration?" and answer it in the negative.

Likewise, no administration of aminopyrine or other drugs has been found to produce agranulocytosis in

experimental animals. In this laboratory Stenn⁶ has tried in several species many sorts of suggested and original methods for sensitizing the bone marrow so that experimental agranulocytosis can be produced, but without success, and the literature yields a similar story.

We suspect that another important disease condition may be produced by some newly popularized chemical agent, presumably therapeutic, namely, "suprarenal cortex atrophy" leading to Addison's disease. One of us⁷ called attention to the fact that this sort of lesion as the cause of Addison's disease was to him a new observation, stating that until a few years ago nearly all cases of Addison's disease that he had seen were the result of tuberculosis of the adrenals but that of the last nine cases examined in this laboratory six had been of the "atrophy" type, better designated as "selective destruction of the adrenal cortex." Since that time of seven more cases of Addison's disease observed here, three were associated with cortical atrophy and four with tuberculosis. According to evidence in published articles and discussions in society meetings, other pathologists seem to have had a similar experience. Thus, Von Glahn⁸ states that since 1926 he has seen five cases of Addison's disease associated with adrenal atrophy, whereas in twenty-four years only six cases, all due to tuberculosis, were observed. A similar experience has been noted in the Mayo Clinic. In 1929 Barker⁹ reported that among twenty-eight cases of Addison's disease twenty-five presented bilateral tuberculosis and three "advanced bilateral atrophy." Dr H. E. Robertson informed one of us in May 1937 that, since Barker's paper was published, of nineteen cases of Addison's disease nine were due to adrenal tuberculosis, one to adrenal calcification of unknown etiology and nine to cortical atrophy.

In view of the close similarity of the lesions in the adrenal cortex in these cases to the histologic features of cinchophen poisoning of the liver and the similarity of their coincidental appearance during recent years, the suspicion was aroused that the selective destruction of the adrenal cortex might have been produced by some drug or other chemical agent. The six cases studied were so scattered in time and place that it was impossible to check up satisfactorily on their histories beyond the hospital records, and these revealed no common condition or therapeutic experience. None of the other writers on cortical destruction of the adrenals have been able to find any reasonable explanation, although none of them seem to have been directing attention to any drug or chemical cause.¹⁰ Susman¹⁰ calls attention to the particular frequency of the cases in women, especially in the age group of from 35 to 45 years, but this throws little light on the etiology. His suggestion that "an accumulation, in the adrenal, of minor atrophic lesions

may be causal in some cases" seems scarcely adequate in view of the marked regenerative capacity of the adrenal cortex. The anatomic manifestations suggest more a massive necrosis in which nearly all the cortex cells are destroyed. Only in those cases in which the destruction is so nearly complete that the regeneration is inadequate does recognized adrenal insufficiency result.

Recently we have seen a case of selective necrosis of the adrenal cortex, not associated with recognized Addison's disease, which seems to demonstrate that organic chemicals therapeutically administered can have an effect on the adrenals similar to the effect of cinchophen and other chemicals on the liver.

A woman, aged 57, came to the University of Chicago Clinics, Oct. 29, 1935, in a critical condition, with a blood pressure of 90 systolic, a high temperature and clinical evidence of pemphigus vulgaris as diagnosed by Dr. Becker. She was able to state that in September 1934 she had been told that she had a rare skin disease, for which a dermatologist gave her, in addition to dietary management, injections of "germanin."¹¹ She died the second day after admission. The blood pressure on the day before death was 90 systolic, 68 diastolic. There was no noticeable cutaneous pigmentation. There were extensive pemphigus lesions in the oral mucosa, so that the existence of pigmentation here could not be determined. Besides the pemphigus lesions in the skin and mucous membranes there were no marked changes in the body except for bronchitis, early bronchopneumonia and the changes found in the adrenals. These were noted during the autopsy to show marked bilateral atrophy of the cortex with apparently normal medulla. Unfortunately the weight and dimensions were not recorded.

Microscopically the changes in the adrenal were very striking and quite the same as those seen in typical cases of destruction of the adrenal cortex associated with Addison's disease, except that the regenerative changes were slight, presumably because the disease had been of shorter duration. In both adrenals the entire cortex epithelium had almost completely disappeared, leaving the original stroma containing only distended capillaries, a moderate number of small round cells and occasional small groups of living cortex cells, which were abnormally large but which seemed not to have as yet formed the characteristic islands of regenerating cells seen in cases of longer duration presenting outspoken Addison's disease. An interesting feature was the presence of a small accessory nodule of cortical tissue outside the adrenal capsule, which had undergone a similar loss of functional cells. Connective tissue stains indicated that there had been little if any new formation of fibrous tissue—merely a condensation of the preexisting tissue. The medulla seemed to be entirely normal, as were the blood vessels.

No changes of significance were found in any of the other organs.

It is unfortunate that this patient was not under observation except in the last hours of life, when a terminal sepsis dominated the picture. The degree of adrenal change was so great that there is no doubt that, had she been free from the fatal pemphigus, the Addison complex would have developed, for the adrenals were fully as much damaged as those in some of the fatal cases presenting typical Addison's disease. This is to be looked on as a case of selective necrosis of the adrenal cortex in which death occurred from other causes before the clinical picture of Addison's disease had manifested itself, despite the serious dermatologic condition with which the woman was

suffering. In view of the history of protracted treatment with germanin our suspicion was aroused that "at long last" we had found a case in which a possible chemical etiology might be established for an adrenal lesion.

Investigation of the nature and effects of germanin revealed the following facts:

First introduced in 1920, and after the demonstration of its remarkable trypanocidal effect in experimental infections, germanin gained wide use in the treatment of human trypanosomiasis. Few undesirable side effects have been attributed to its use in the doses commonly employed for this purpose. Of course late effects, especially Addison's disease, might be missed in African natives, but a considerable number of treated Europeans have been followed for several years, with cures and no obvious delayed effects attributable to the drug. It is natural that the successful treatment of trypanosomiasis should have been followed by tests of its efficacy in other diseases, among them kala azar. The reports of two fatalities attributed to the drug put a damper on enthusiasm.

Veiel¹² in 1931 introduced germanin in the treatment of pemphigus vulgaris, and there have been many reports of remissions and cures, as well as others telling of failures. It has come to be appreciated that germanin is not a sure cure, but, considering the generally hopeless outlook in pemphigus, its use has been thought justifiable in spite of certain drawbacks.

Soon after 1921 it was appreciated that germanin has a cumulative effect, being detectable in the blood and urine for a considerable period. It also became obvious that the drug is a renal irritant, usually causing albuminuria and often the appearance in the urine of hyaline and granular casts, and sometimes of red cells. That germanin may cause blood destruction has long been known. A recent report¹³ of the development of leukopenia with agranulocytosis following germanin points to a depressant effect on the bone marrow.

On the whole, autopsy reports, either on human beings or on experimental animals treated with germanin, are few and incomplete. There has been evidence of a tendency to hemorrhage, and focal necroses with fatty changes have been observed in the liver. Accounting for the urinary abnormalities, the most constant and striking condition reported is epithelial degeneration with necrosis in the renal tubules. Few systematic studies have been reported, and no reports were found of microscopic study of the adrenal glands.

We have given a series of laboratory animals (rats, rabbits and guinea-pigs) germanin injections—intravenous and subcutaneous. In all three species large (lethal and sublethal) doses caused serious injury to the kidneys, liver, myocardium and adrenal glands. A graded series of sublethal doses—down to amounts comparable to the dosage in human disease, was given to guinea-pigs. With these smaller doses it was evident that the kidney and adrenal were injured to a greater extent than the liver and myocardium. While in most instances the renal damage probably caused the fatal outcome or progress in cachexia, in a few guinea-pigs renal changes were slight when the adrenal glands were seriously damaged. Those glands usually showed

¹¹ Germanin also called Bayer 205 is a carbamide of meta aminobenzoyl meta aminoparamethylbenzoyl 1 naphthylamine 4, 6, 8 trisulfonic acid. The attending physician Dr. M. L. Weinstein has kindly furnished the information that the first dose of germanin (one-half ampule) was given Dec. 20, 1934; another half ampule December 22 and then full ampule doses on nine occasions between December 24 and March 14. Other injections of one ampule were made June 11, September 7, 14 and 24 and October 4 and 24—a total of 16 Gm. in ten months.

¹² Veiel, F. Die Behandlung des Pemphigus mit Germanin. *München med. Wchnschr.* 78: 2047-2048 (Nov. 27) 1931.

¹³ Geyer, Hans. Ueber die Behandlung des Pemphigus und der Dermatitis herpetiformis Dühring mit Germanin und über die dabei beobachteten Nebenerscheinungen. *Acta dermat. venerol.* 16: 328-342 (Nov.) 1935.

a wide band of necrosis in the fasciculate zone of the cortex. In the nonlethal dosage this was often associated with regeneration, evidenced by very numerous mitotic figures. With the doses and time intervals so far employed, the picture of so-called adrenal atrophy has not been produced. However, the qualitative similarities suggest further experiments, which will be undertaken and reported with more details of the experiments already completed.

These experiments, demonstrating a marked and perhaps even a special susceptibility of the adrenal cortex to one chemical agent, raise interesting questions. It is improbable that such a rarely used drug as germanin is responsible for many cases of Addison's disease. However, in a study of the toxic potencies of drugs, the adrenal glands are rarely considered. It would seem probable that therapeutic chemicals in more common use than germanin may be found to have a special injurious effect on the adrenal cortex, especially under conditions of unusual susceptibility.

That the pemphigus was responsible for the adrenal lesions in our case is highly improbable, in view, first, of the experimental evidence that germanin has a markedly toxic effect on the adrenals in animals, and, secondly, of the absence of such lesions in the cases of pemphigus so far reported. In the dermatologic literature the autopsies are usually summarized quite briefly and usually make no mention of the adrenals. The only recent American report that we have been able to find is that of Tobias,¹⁴ who describes a fatal case in a child of 12 treated with germanin but complicated by endocarditis and sepsis. Foldvari¹⁵ of Budapest tabulates the autopsies in thirty-seven cases. They are presented briefly, but he states that they "present very little in common." Since endocrine dysfunction has been blamed for pemphigus, he apparently paid especial attention to the endocrine organs but found no constant variation from normal. The same conclusions were reached by Lucien Hudelo¹⁶ and Leo Kumer¹⁷.

CONCLUSIONS

Selective necrosis of the adrenal cortex seems to have become an increasingly common cause of Addison's disease in recent years. The similarity of the changes seen in these adrenals to the changes in toxic necrosis of the liver with resulting "acute yellow atrophy of the liver," which is so often produced by cinchophen, and to the selective destruction of marrow elements by aminopyrine and other drugs, leading to agranulocytosis, suggests the probability that necrosis of the adrenal cortex may likewise have become more frequent of late because of the action of some drug or chemical in persons with a particular idiosyncrasy.

In support of this hypothesis we report the case of a woman who had been treated for pemphigus with "germanin," or "Bayer 205," and died with almost complete selective necrosis of the adrenal cortex, identical with that seen in cases of Addison's disease. Animal experiments have shown that this drug will produce a marked destruction of the adrenal cortex cells similar in character to the changes seen in our case. While germanin cannot be incriminated in the cases of

Addison's disease from selective cortical necrosis of the adrenals so far reported, these clinical and experimental observations do support the hypothesis that drugs or chemicals may be responsible for many if not all the cases of Addison's disease of this type. Consideration of this possibility in history taking in cases of Addison's disease may serve to reveal the agents responsible for the adrenal damage.

STUDY OF THE TOXICITY OF ORTHO-TOLUENO-AZO-BETA-NAPHTHOL, AN OIL-SOLUBLE FOOD DYE

DAVID R. CLIMENKO, M.D., PH.D.

COLD SPRING HARBOR, N. Y.

Considerable interest has centered about ortho-tolueno-azo-naphthol¹ since it has been used in the processing of citrus fruits and questions have arisen regarding the potential deleterious action on consumers of treated fruit. This study was undertaken to elucidate the issues that have arisen. The present report, for the purposes of brevity, will omit all detailed protocols, growth curves and blood pictures, which will be published in a subsequent paper.

The dye under investigation has the chemical structure

It is soluble in fat and fat solvents, it is completely insoluble in water. It is estimated that from 1 to 5 mg. of the dye is present on the skin of a treated orange. No dye is to be found in the edible portion of the fruit, all of it is in solution in the outer coat of the rind.

ACUTE TOXICITY

Studies on acute toxicity were carried out on dogs, rabbits and rats. The dye was administered orally with food, orally in capsules, by stomach tube in acacia suspension, intramuscularly in oily solution and intravenously in acacia suspension. The results are summarized in the table.

The symptom complex that resulted from the oral administration of large doses of the dye to dogs might be referred to irritation of the gastro-intestinal tract. Retching and vomiting usually occurred within two hours of the administration and persisted for a short time. This was followed by a variable period of anorexia, associated with severe diarrhea, which lasted from one to five days, depending on the size of the dose administered. The stool was watery and deeply stained by the dye, it contained large quantities of mucus. A method which depended on the chloroform extraction of the dye from body fluids was used, and the presence of the dye in dilutions of 1:250,000 could be demonstrated. In spite of this fact, no trace of the dye could be found in the blood or in the urine of the dogs at any time after administration. Animals which had received the maximum oral dose failed to show any gross or microscopic pathologic changes other than slight hyperemia of the mucosa of the gastro-intestinal

tract, associated with evidence of marked hypersecretion. In no instance was there any indication of dye staining of tissues.

Results obtained from the oral administration of the dye to rabbits were more variable, and evidence of absorption from the intestine was observed in a number of instances. Of course no vomiting occurred, but signs of gastro-intestinal irritation were to be seen in the apathy, anorexia and diarrhea, associated with a fall in the body weight, which invariably followed the administration. A number of the fatalities listed for this group cannot be attributed to the toxic action of the dye, for example, in a group of animals which received a dose of 15 Gm per kilogram one death occurred. This death took place within twenty minutes after the administration, and postmortem examination revealed edema of the larynx, together with pulmonary edema, and was obviously the result of traumatization that occurred during the passage of the stomach tube

and a normal growth curve was reestablished, the animals which were killed at this time for examination showed no discernible pathologic lesions other than the presence of the dye in the adipose tissues. When fatalities occurred as the result of the administration of the dye, death took place from eight to thirty days after the administration. The animals failed to reestablish a normal growth curve and had almost complete anorexia. Pathologic changes consisted of massive dye staining of the subcutaneous adipose tissues, diffuse parenchymal degeneration in the liver and early nephrotic changes in the kidney. Death always resulted from superimposed bronchopneumonia. Dye could be demonstrated in large quantities in the liver, the spleen and the kidneys.

The intramuscular administration of the dye proved to be unsatisfactory because of the low solubility in oil and because of the irritant effects both of the solvent and of the dyestuffs.

The acute toxicity resulting from the intravenous administration of the dye was studied in dogs and in rabbits. No dogs died as a result of the administration of doses up to and including 180 mg per kilogram, whereas a number of rabbits died after receiving doses as small as 40 mg per kilogram. The results are summarized in the table.

The following sequence of events occurred after the administration of a dose such as 200 mg per kilogram of the dye in acacia suspension to a dog. Within twenty minutes there was marked apathy, associated with hypersalivation. The hypersalivation persisted and increased in intensity, retching occurred and the respiratory rate was increased. Shortly afterward repeated vomiting took place, and dye-stained frothy material was brought up. Diarrhea occurred, and watery stools containing quantities of the dye were passed. These signs of gastro-intestinal irritation persisted for one or two days, during which time the animal suffered from complete anorexia. By the fourth day it had made a complete recovery and could not be distinguished from a normal animal.

When the dye was administered intravenously to a dog, it disappeared from the circulating blood within fifteen minutes after the completion of the injection. About the same time it appeared in the bile from the common bile duct. At no time could dye be demonstrated in the blood taken from the renal vein or in urine collected from the ureter.

When death occurred as a result of the intravenous administration it took place any time from twenty minutes to thirteen days after the completion of the injection. When death followed immediately after the injection the principal pathologic change was pulmonary edema. When an interval of days intervened, examination showed the presence of free fluid in the peritoneum, congestion of the peritoneal vessels, dye staining of the omental fat, congestion of the liver, inflammation of the mucosa, the duodenum, the stomach and the upper portion of the jejunum, and patchy areas of consolidation in the lungs. Microscopic examination demonstrated parenchymal degeneration in the liver and bronchopneumonia.

Animals which recovered from doses of 200 mg per kilogram were killed thirty days after administration. No pathologic changes could be demonstrated in these animals.

The picture produced in rabbits was essentially similar to that observed in dogs save for the fact that it

	180	0	0	0
	200	3	3	0

Deaths which could be directly attributed to the administration of the dye occurred from three to five days after administration, during which time there was complete anorexia and intense thirst. Postmortem examination showed irritation of the entire gastro-intestinal tract, cloudy swelling of the parenchymal cells of the liver and of the collecting tubules of the kidney, and generalized diffuse dye staining of the adipose tissues. In no instance was there any indication of dye staining in the tissues of the central nervous system. Approximately 25 per cent of the animals of this group, regardless of the amount of the dose, excreted small quantities of the dye in the urine, dye could be demonstrated in the blood of these animals. The majority of the animals, however, failed to show any trace of dye either in the blood or in the urine at any time after administration.

After the administration of the dye the rats suffered from slight diarrhea and loss of body weight. The dye was present in the feces in large quantities within twelve hours after completion of the administration. Traces of the dye were present in the urine, but it is difficult to state with certainty whether or not this was due to fecal contamination. The great majority of the animals made a complete recovery within five days,

no time after the intravenous administration could the dye be demonstrated in the stomach. It was invariably present in the liver, the duodenum and the entire gastrointestinal tract. Death was always preceded by a stage of muscular excitability followed by tetanic convulsions.

It was thought advisable to compare the toxicity of ortho-tolueno-azo-beta-naphthol with that of an oil-soluble food dye such as benzeneazo-b-naphthylamine or tolueneazo-b-naphthylamine, which are in common use oil yellow AB and OB. Eighty per cent of the rabbits recovered from the intravenous administration of a dose of 40 mg per kilogram of these substances, 80 per cent recovered from a dose of 80 mg, and there were no recoveries from doses of 100 mg or over. One dog in a group of three recovered from the intravenous administration of a dose of 120 mg per kilogram, while all the members of another group of three died after a dose of 180 mg. In all instances in which death occurred there was marked pulmonary edema and dye staining of all the adipose tissues and of the tissues of the central nervous system. Studies on oral toxicity with these dyes were confined to rabbits. No animal survived a dose of 5 Gm per kilogram or more.

CHRONIC TOXICITY

Rabbits and rats showed no serious ill effect from the daily administration of doses up to and including 100 mg per kilogram a day over a period of six months. Postmortem examination of these animals in a few instances showed a very slight degree of cloudy swelling of the parenchymal cells of the liver. In no instance was there any indication of hyperplasia or neoplasia in the urinary tract. All the animals showed a moderate degree of dye staining, limited to the adipose tissues.

In the first study on chronic toxicity the dye was administered to dogs as a dry powder in gelatin capsules. By the end of the third month these animals died of severe hemorrhagic gastro-enteritis and complete anorexia regardless of the size of the dose. They showed marked parenchymatous degeneration of the liver and of the collecting tubules of the kidney, ulceration of the gastric mucosa and petechial hemorrhages throughout the mucous membranes of the entire gastrointestinal tract. It was felt that these lesions resulted primarily from the irritating effect of the concentrated dye on the gastro-intestinal mucosa, and accordingly another series of experiments was started, in which the dye was administered as a 1.5 per cent solution in olive oil. The animals showed varying degrees of anorexia and consequent loss in body weight but no significant pathologic lesions.

SUMMARY

The acute toxicity of ortho-tolueno-azo-beta-naphthol is very low. While it is difficult to draw analogies between the action of a chemical agent on experimental animals and its action on man, it should be pointed out that a dose of 20 Gm per kilogram, which was the maximum dose after which recovery took place, is the equivalent of a dose of approximately $2\frac{1}{2}$ pounds (1 Kg) of the dye for a man weighing 60 Kg. The toxicity of the dye compares favorably with that of yellow AB and yellow OB dyes, which are in common use for the coloration of butter.

As to chronic toxicity, no serious deleterious effects resulted from the daily administration of doses up to 100 mg per kilogram a day over a period of six months. This represents the daily administration of the total dye content of 1,200 treated oranges to a man weighing 60 Kg.

Clinical Notes, Suggestions and New Instruments

DERMATITIS CAUSED BY DICTAMNUS ALBUS (GAS PLANT)

AN EXAMPLE OF PHOTODERMATITIS

CLAUDE L. CUMMER, M.D. AND RICHARD DEXTER, M.D.
CLEVELAND

This report is made because *Dictamnus albus* is a rather commonly cultivated garden plant and we have been unable to find any mention of its irritating property in the literature. Furthermore the requirement of the sun's rays to produce the irritation is of distinct interest.

Fig 1—Appearance of eruption at time of first visit

In July 1935 a man noticed an eruption on his forearms (fig 1). Two days previously he had been working in his garden in the hot sun. *Rhus toxicodendron* was suspected as the cause but the patient was certain that there was none in or near his garden. He remembered a similar outbreak on the skin which had appeared in the early summer two years previously.

Fig 2—*Dictamnus albus* in natural habitat

There was no eruption on the hands but this was readily understood since gloves had been worn. Recalling a chance inquiry made some years previously as to whether or not the gas plant could irritate the skin (a question which could not be answered then) we asked whether there were any of these plants in his garden. He replied that there were that he had cut off the stalks two days before the appearance of the eruption.

tion, and that in removing them he had carried them across his forearms. He remembered that the tops, i. e., the seed pods, had rested on the arms at the sites of the eruption.

Unfortunately the stalks had been thrown away, and it was too late to secure any from other gardens for testing during 1935, but a few days later another patient consulted us with a similar eruption and practically the same history. The eruption in both cases differed definitely from that produced by *Rhus toxicodendron*, members of the *Rhus* family, the prim-

Fig. 3—Blossoms of *Dictamnus albus*

rose family or other commonly encountered plant irritants. There were patches of irregular size and shape in which the skin was dusky red, and occasional bullae about the size of navy beans, occasionally two or three grouped together rather closely. The subjective symptoms were notably slight, there being little or no itching, burning or other discomfort. As the bullae involuted and the erythema subsided, conspicuous pigmentation or staining resulted, which persisted for several weeks or months.

The plant was in full bloom May 30, 1936. Photographs were taken of it in its natural location in the garden (figs. 2 and 3), and a day or so later portions of the blossoms, stem, leaf and rather viscid stem juice were used for making patch tests. To our disappointment, no reactions occurred, and we concluded that the seedpods probably contained the irritant. Accordingly, June 2, when seed pods were formed (fig. 4), they were used for patch tests, portions being applied to the skin with the minute needle-like covering next the skin and with the inside of the pod next the skin. Also contact tests in which portions of the stem and the leaf were used were repeated. At this time juice could not be expressed from the stem, the interior of which was quite pithy. After these portions of the plant had been in contact with the skin for twenty-four hours, the cellophane and adhesive covers were removed and the skin was found to be entirely normal. The needle-like prickles had made a perfect impression into the skin but even with this insult there was no irritation.

We might have felt that our suspicion of the plant was unfounded had it not happened that while securing parts of the plant the patient remembered distinctly having been brushed accidentally on the left temple with one of the seed pods, at which point a dusky erythematous eruption appeared forty-eight hours later. This gave us our clue, i. e., that the irritating factor required either the sun's rays or exposure to air to render it effective. The resemblance to the production of berlock dermatitis is obvious.

Accordingly the pod was rubbed on the left forearm, and this area was covered as for a contact test, while an area on the right arm was rubbed with equal vigor and kept exposed to the sun and air as the subject worked in his garden for two hours. About sixteen hours later there was an erythematous patch on the right arm, which had been exposed to the sun. This showed bullae the following day (fig. 5). The left arm showed no reaction.

We were still in doubt as to whether exposure to air or the sun's rays served as a precipitating factor, so areas on the unaffected arm were rubbed with portions of the seed pods as before. The upper part was covered with cellophane and adhesive to exclude air as much as possible, the middle with two layers of gauze and a layer of dark green cloth sewn on to exclude the sun's rays but held in place loosely to admit air. The lower part entirely uncovered and exposed as before to the sun's rays for a period of about two hours. The last mentioned area showed erythema followed by bullae, while the other two sections showed no reaction whatever.

The question then arose as to whether the plant irritated all skins or not. On the arm of one volunteer (B. D.) the seed pod was rubbed and the area was exposed to the sun with no resultant irritation. On another (C. L. C.) there was no irritation, but about four days later, definite discoloration of the skin appeared as a light brown patch studded with pinhead size red macules. The pigmentation has lasted over three months.

It was thought that possibly the toxic action could be activated by ultraviolet radiation as well as by the sun's rays so the seed pods were rubbed on the arms of two individuals (the original patient and the subject who had shown slight pigmentation after exposure to the sun's rays), but in neither case was there any reaction.

In an attempt to extract the irritant, seed pods were soaked in (a) 95 per cent ethyl alcohol and (b) ether. The extracts were filtered and applied to the arms of the same subjects. Also the seed pods were cut up and soaked in water, and the mixture was distilled with a condenser. Oily drops were found floating on top of the distillate, which had the same lemon-like odor as the plant. The distillate was thoroughly shaken to suspend the oil. Then to three separate sites on the forearms of these subjects were applied (a) alcoholic extract, (b) ethereal extract and (c) distillate. The arms were exposed to the sun but there were no reactions.

Dictamnus is a member of the Rue family. According to Bailey's *Cyclopedia*¹ the names commonly employed are gas plant, burning bush and *Fraxinella*. The genus includes an old garden plant which has a strong smell of lemon and gives a flash of light on a sultry summer evening when a lighted match is held under a flower cluster near the main stem. It is a vigorous, symmetrical, hardy herb with glossy leathery foliage surmounted by long, showy terminal racemes of good sized flowers. The leaves are alternate, odd pinnate, and the leaflets ovate, serrulate, dotted with oil glands. There are four varieties: *purpurea*, with large, dark colored flowers, *rubra* with rosy purple flowers, *giganticus*, a large plant, and *caucasicus* a giant form with racemes twice as long as those of the common form.

Professor Bacon² of the School of Pharmacy of Western Reserve University states that the lemon-like odor indicates citral and possibly other terpenes, which would account for the burning and the name gas plant.

Fig. 4—Seed pods of *Dictamnus albus*

1 Bailey L. A. *Standard Cyclopedia of Horticulture* vol. 1 p. 1004
2 Personal communication to the authors

Pammel³ says that *Dictamnus albus*, a viscid glandular plant with strong aromatic scent, is commonly cultivated but makes no mention of irritating effects. He refers to another species of the Rutaceae, the common rue (*Ruta graveolus*), a native of Europe sometimes seen in country gardens, and so acrid that it will even blister the hands."

In his classic monograph James C. White⁴ mentions among offenders in the Rue family Rutaceae *ailanthus-glandulosa*, *Pilocarpus pennatifolius* and *Ruta graveolus* but not *Dictamnus albus*.

Castellani and Chalmers⁵ list the same three members of the Rutaceae family as did White, and in addition *Haplophyllum tuberculatum* (Forskul, 1775) and *Rue montana*. They state that in the Rue group the poisonous principle is apparently volatile but acts mainly when the plant is handled. No mention is made of *Dictamnus albus*.

Fig. 5.—Appearance of arm seventy-two hours after it had been rubbed with *Dictamnus albus* seed pod and had been exposed to sunlight while the patient worked in the garden for two hours.

This plant is not included in Weber's⁶ list of cutaneous irritants. Careful search of the usual bibliographic indexes fails to give any references to *Dictamnus albus* as a skin irritant. Inquiry in 1935 by correspondence with Dr. A. F. Sievers,² senior biochemist of the Bureau of Plant Industry, elicited the answer that no cases of poisoning by *Dictamnus* had come to the attention of the bureau.

SUMMARY

Dictamnus albus, commonly known as the gas plant, is a showy garden plant commonly grown in certain parts of North America. It can cause a skin irritation. The toxic factor is apparently a photosensitizer for contact with the plant does not cause irritation unless it is followed by exposure to the sun's rays. The effects on the skin comprise erythema and bulla formation. Subjective symptoms are slight or absent. In the affected areas, staining persists for weeks or months. The resemblance to berlock dermatitis is obvious.

7 Since this article was submitted for publication L. F. Weber's article on External Causes of Dermatitis: A List of Irritants has appeared (Arch. Dermat. & Syph. 35: 129-133 [Jan.] 1937). In it is found reference to *Dictamnus fraxinella* producing irritation by exposure to the stalks, leaves or flower (Baronovsky. Russk. vestnik dermat. Jan. uary 1929, p. 58).

Bacteremia and Septicemia—Normally, the blood has a remarkable capacity for rapidly clearing itself of microorganisms. At least, this has been abundantly proved experimentally with the lower animals when large numbers have been introduced directly into the blood, and it doubtless holds true for human beings as well. Furthermore organisms, particularly streptococci of low virulence, may be intermittently present in the blood, as detected by cultures when there is no clinical evidence of infection and especially in persons with chronic foci of infection about the teeth and tonsils. This constitutes bacteremia and probably occurs more frequently than is ordinarily surmised. However, when the blood is invaded by organisms of high virulence and the clearing mechanism is inadequate or fails, with possibly some actual proliferation and the production of toxins, this tissue may be regarded as being infected which constitutes septicemia.—Kolmer John A. Etiology, Prophylaxis and Treatment of Surgical Septicemia, Arch. Otolaryng. 26: 59 (July) 1937.

Special Clinical Article

PROTAMINE INSULIN

CLINICAL LECTURE AT ATLANTIC CITY SESSION

ELLIOTT P. JOSLIN, M.D.

BOSTON

There are probably 70,000 more diabetic patients in this country using insulin today than there were a year ago, and I attribute this increase chiefly to the discovery of protamine insulin by Dr. Hagedorn of Copenhagen. His discovery stimulated the use of insulin and insulin it is which has lessened coma and made it inexcusable, has raised the life expectancy of 10 year old diabetic children from two years to 31 1/2 years, and has trebled the duration of diabetes for all diabetic patients and even deferred premature arteriosclerosis by two years or more. The simplicity and convenience of administering insulin once a day have appealed to the diabetic public, and is it any wonder that they have turned to it or that I should feel still more strongly now than a year and a half ago that, in recognition of this extension of the use of insulin—an indirect benefit—and of direct advantages later to be enumerated, the present epoch of diabetes should be named the Hagedorn era?

More than 1,250 of my patients, of whom 342 are under 20 years of age, now depend on protamine insulin. They have been treated with one variety or another of protamine insulin (supplied to me most generously by Dr. Hagedorn, Eli Lilly & Co., and E. R. Squibb & Sons), but chiefly with protamine zinc

TABLE 1.—Age of Patients Using Protamine Insulin Alone and with Regular Insulin and the Percentage of Each to the Total in Each Age Group

insulin between August 1935 and May 1937. By protamine insulin in this paper I mean protamine zinc insulin.

No patient who began the treatment of diabetes with protamine insulin has stopped it except as he no longer required any insulin. Fifty-three per cent, or 657, of the patients take protamine insulin alone and the remaining 593, or 47 per cent, use regular insulin and protamine insulin administered in separate doses before breakfast. A few, largely for emergencies, such as coma, surgery or infections, supplement the morning dose with regular insulin later in the day and a few for experimental purposes take protamine insulin at other periods in the day.

Read in the Medical Division of the General Scientific Meetings at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 8, 1937.
The tables in this paper were prepared by Mr. Herbert H. Marks and his co-workers in the Statistical Department of the Metropolitan Life Insurance Company. The preparation of the cards for their computations was under the supervision of Miss Lucille Winterbottom of the George F. Baker Clinic.

Quite consistently the need for regular insulin plus protamine insulin decreases as age advances. Thus under 20 years of age the percentage is 80.4 requiring both varieties, but above 60 years it is 17.6. Protamine insulin sufficed for only 19.6 per cent under 20 years of age but was adequate for 82.4 per cent above 60 years.

During these twenty-two months thirty-seven patients are conspicuous for giving up protamine insulin and returning to regular insulin. However, eight of this group already have found that protamine insulin is preferable and so have returned to it. Of the remaining twenty-nine cases there are eight outstanding patients who had meticulously and intelligently treated their disease with regular insulin for nine or more years with from two to four doses daily and in this way lived usefully and happily, adjusting their insulin requirements to the needs of their several occupations and peculiar diets and the amount of exercise. A second group of three patients habitually took liberties with their diets but find that with protamine insulin once a day they are at a loss what to do if they wish to break over dietary bounds. Five other patients have given up protamine zinc insulin because although they

of experience with two, three or four daily doses of regular insulin, have learned how to keep the urine sugar free for the greater part of the twenty-four hours by adjusting insulin to the needs of the hour as determined by variations in diet, rest and exercise.

Mr. T., aged 73, with diabetes of nine years' duration takes regular insulin 24.0-18.2 units, for years he has tested his specimens four times a day and has varied his night dose from 0 to 4 units and thus avoids insulin reactions and usually wakes up sugar free. He is perfectly happy with this regimen.

Excellent as protamine insulin is, it does not live brains, and a single injection before breakfast will not counterbalance an unusual meal or an unaccustomed period of activity. But for the 98 per cent of diabetic patients the discovery of protamine insulin is a wonderful boon and the great majority of letters I receive are filled with gratitude for it.

Children as well as adults welcome a treatment of diabetes which requires only one injection of insulin daily. They appreciate the comfort and relief from embarrassment by being spared two or more injections often away from home. Only those who see many diabetic patients will fully realize the truth of these words.

had reactions with regular insulin the reactions with protamine insulin were more disagreeable on account of their greater duration and the accompanying headache and nausea. There are three others whose occupations were so peculiar, so strenuous and so variable from day to day that it was difficult to make the adjustment with protamine insulin. The remaining ten cases represent poor judgment on our part in trying the effect of too many different preparations of protamine insulin with one patient and thus creating confusion, in carrying out the transfer in too short a period or in permitting its use by those somewhat mentally deficient, or because of unusual medical complications.

In the Section on Pharmacology and Therapeutics on Friday I shall discuss this group of twenty-nine patients, or 2.4 per cent of the total number, more in detail. But I will say now that before changing any patient from regular insulin to protamine insulin, even though the patient is well instructed, one should have a preliminary period of at least three days' observation to find out how satisfactorily regular insulin is working. One may find that the hly is not as perfect as it is painted and may need a little touching up after all. Such a period serves as a most useful background and allows comparison with the action of protamine insulin.

It is a privilege for physicians to prescribe protamine insulin and for diabetic patients to take it. I prescribe it for all untreated patients with diabetes who need insulin, but I do not urge it on any one accustomed to regular insulin, much less attempt to persuade that select body of individuals to employ it who, after years

But it is because I am thinking of the larger group of diabetic patients who heretofore have not taken insulin at all but really need it, that I am especially thankful for protamine insulin with its single injection. Although there are 70,000 more diabetic patients taking insulin today than there were a year ago, I estimate that there are still one or two hundred thousand persons with mild diabetes in this country who ought to be prevailed on to take insulin in the early stages of the disease. In this way alone can most of them be prevented later from acquiring moderately severe or even severe diabetes. The distressing complications of the disease which the use of insulin might avert should be considered. Naunyn was right when he wrote that the mild case, neglected, is apt to become severe, but that the severe case carefully treated usually does not progress. And I will enlarge for a moment on this matter of diabetic control before entering into the details of treatment with protamine insulin.

The control of diabetes in this country is poor, and needlessly so. Here are my proofs, and to avoid criticism they are based chiefly on my own clientele.

1 *Experience from Physicians with Diabetes*—My diabetic physicians under the age of 40 have less than one fourth the mortality of all my diabetic patients of similar age, those between 40 and 59 years have less than one half the mortality as compared with their corresponding age group, and even above 60 the physician does better. My diabetic physicians are a living indictment of the inadequacy of my diabetic treatment.

Must a diabetic person become a physician if he wants to live? If you do not think so, then you must teach the patient all the diabetic tricks of the trade

2 Experience from Diabetic Coma—Deaths from coma are as inexcusable as from diphtheria. Mr. Herbert H. Marks of the Statistical Department of the Metropolitan Life Insurance Company recently wrote me "Outside of the large centers, the coma situation is ten years behind the times, in that the percentage of deaths from coma is as high today as it was in the better treated groups ten years ago." But I will add to the force of Mr. Marks' statement. Since the advent of insulin I have treated 1,163 children with diabetes and of these, during the last fifteen years in one place or another of the world, 104 have died. Now it should be borne in mind that a death from coma is needless. At the Children's Hospital no child, and at the Deaconess Hospital but one child since the discovery of insulin, has died of coma. There was no death of a diabetic patient under 19 years of age from any cause in Boston in 1935. Yet, during the first five years of insulin, 1922-1927, there were among my child patients a total of thirty-five deaths, of which

The degrees of control of the diabetes of patients on protamine insulin were excellent in 10.2 per cent, good in 60.0 per cent, fair in 27.1 per cent and poor in 2.7 per cent. It mattered comparatively little whether the patients had or had not previously taken insulin. Certain previously untreated but not recently diagnosed cases showed the best control, presumably because they were mild cases anyway.

The improvement in control of the diabetes with protamine insulin is most strikingly shown in table 3 for those patients who had never taken insulin before but is even three times more satisfactory over those who had taken regular insulin, if deductions are limited to the excellent and good classes. On the other hand, other studies make it plain that if a patient actually does poorly or only fairly well with protamine insulin, he probably did very poorly before it was begun.

Experience in the use of protamine insulin helps. Now it is possible to control patients distinctly better than it was with protamine insulin before Oct. 1, 1936. This is illustrated in table 4. In the early period 64 per cent but now 73 per cent show good or excellent control.

* Excludes newly diagnosed cases begun on protamine insulin

thirty-two, or 91 per cent, were from coma. During the second five year period, 1927-1932, there were twenty-seven total deaths and nineteen, or 70 per cent, from coma, and during the recent five year period, 1932 to date, there have been forty-two deaths, and of these, eighteen, or 43 per cent, were from coma. Even with the advantage of insulin the deaths from coma in childhood in this recent five year period is greater than the percentage of deaths from coma, 42 per cent, reported for all my diabetic patients in the eight years before the discovery of insulin. Does this show an adequate control of diabetes?

3 Experience Disclosed by Studies of Diabetic Patients Treated with Protamine Insulin—A statistical study of 1,250 of my patients taking protamine insulin has been made with the help of Mr. Marks. Originally undertaken for an investigation of protamine insulin alone, it has revealed how inadequate the control of diabetes is in a larger group of diabetic patients. My cases were divided according to the degree of diabetic control into four classes. Excellent, meaning thereby blood sugar normal, no glycosuria. Good blood sugar tests slightly above normal twenty-four hour glycosuria under 15 Gm. Fair blood sugar tests frequently above 200 mg but under 300 mg, glycosuria between 15 and 30 Gm in twenty-four hours. Poor erratic and high blood sugar values rising above 300 mg and twenty-four hour glycosuria in excess of 30 Gm. The tabulations are quite detailed and most of them will be published, but at this time I will endeavor to sketch the results in broad lines.

Age plays an important role in the degree of control of diabetes with protamine insulin in that those above 40 years of age did better. The dividing line is 40 years. The number in the excellent and good groups differ little between 20 years and younger, and from 20 to 39 years, although definitely less than above the age of 40. Between 40 and 59 and 60 and over the control is about the same.

The degree of control of the diabetes was distinctly better with those using protamine insulin alone than with those who employed both regular insulin and protamine insulin. This might be expected because more of the milder cases and recently diagnosed cases fall into the group of protamine insulin alone. The results are depicted in table 6.

These tables, however, show me that the control of cases could be still further advanced. I believe that more strenuous treatment can bring this about and it can be accomplished only by closer cooperation between patient and physician. The possibility of and the advantage of better control must constantly be held up before the patient.

The duration of action of protamine insulin is from three to four times as long as that of regular insulin, and even longer (fifty-seven hours), as shown at the Mayo Clinic. Its action is less precipitate and less vigorous at any given moment. Regular insulin 70 units, administered in 10 unit doses before meals at 8 a.m., 12 noon and 5 p.m., might render utilisable 150 Gm of carbohydrate, but protamine insulin in like quantity in a single dose before breakfast would find

difficulty in doing so. If the meals are spread further apart over eleven or twelve hours and a trifling lunch of from 5 to 15 Gm of carbohydrate is insisted on in the forenoon, afternoon and at bedtime, perhaps with a little protein, the problem might be solved. All these lunches may not be necessary. Rarely orange juice may be needed on rising, in other words, less

* Age when protamine insulin was begun.

† Age not stated in three cases.

Protamine insulin acts slowly but steadily. A patient can start with protamine insulin and with increasing doses of protamine insulin show considerable glycosuria or increasing glycosuria for several days, and yet with the same dose of protamine insulin ultimately the glycosuria will clear and the dose require reduction. That is the reason why it is so essential that patients come into the hospital for observation in case one must work quickly with them or at least remain under close observation. In general, one should change the dose of protamine insulin slowly, not expecting the effect to develop for one, two, three or even more days, because the action is certainly cumulative, though for how long I cannot say.

Exercise reduces the need for regular insulin but still more for protamine insulin. This is so because with protamine insulin carbohydrate is more uniformly burned during the twenty-four hours, and, although the process is slow, it is constantly going on as in health. A normal man can withstand considerable demands on his glycogen reserve and far more than the diabetic patient with his meager supply. Nevertheless the Marathon runner or the football player knows that he can easily exhaust his carbohydrate supply and today takes great pains to replace it. The

diabetic patient with protamine insulin must take even greater pains and far more than the diabetic patient with regular insulin, first, because he has been and is utilizing his carbohydrate better and, in consequence, the reserve supply is lower, and, secondly, because the protamine insulin is constantly acting and a single replenishment of carbohydrate will help but for a short period and, therefore, repeated lunches are necessary. The diabetic subject on regular insulin lessens his insulin when he knows that he is to play a game of golf. It is a diabetic proverb that a game of golf is worth 5 units, and so the diabetic person can reduce his morning dose by this amount. Not so with the diabetic patient on protamine insulin. Protamine insulin acts so slowly that reducing the intake 5 units one morning may not have its effect for a day or two. Consequently, to avoid precipitating a reaction from unusual exercise the diabetic patient on protamine insulin, instead of reducing insulin, must increase food and increase it at hourly intervals.

It is very simple for the diabetic person who has never heard of regular insulin to offset the effect of exercise. He learns to match food with his exercise almost involuntarily. For the dyed in the wool diabetic person accustomed to regular insulin trouble frequently occurs, because the patient somehow does not grasp the new way of treatment. With such diabetic subjects I almost got out of patience until I fixed over my bath

room and then discovered that even after nine months I would turn to that part of the wall to shave where for thirty years the shaving mirror had hung.

Reactions with protamine insulin are, on the whole, less frequent and less severe than with regular insulin. On the other hand, they are more subtle in onset. Last

summer not one child of the 120 at the Clara Barton Camp required dextrose intravenously and on no occasion was it necessary to call a physician to treat a patient with a reaction. This was not the case before.

the introduction of protamine insulin. Yet, within twelve hours of my writing this statement, a patient was brought to the hospital in a reaction due to protamine insulin. The untoward features of a reaction to protamine insulin are headache and nausea. The latter the physician dreads because it complicates the differential diagnosis between a reaction, diabetic coma and appendicitis. As said elsewhere, reactions must be treated with a repeated administration of carbohydrate. With intelligence they can be largely avoided, as experience with many patients shows, but model patients occasionally have them.

My standard diet for some years has contained, on the average, 150 Gm of carbohydrate. With children it has risen quite a little above this, particularly because of those in undernutrition, approaching or actually in dwarfism. Last fall the diets generally rose, but it soon became evident that the patient with protamine insulin did less well, on the whole, with carbohydrate above rather than below 150 Gm. On several occasions I failed to secure the anticipated good effect of protamine insulin because I made a vital mistake. At the same time that I changed to protamine insulin I had raised the carbohydrate, thus introducing two variables into the diabetic picture. Soon I saw that I was doing wrong and now I hold to the diet on which the patient was living comfortably but change the insulin. Later, in some instances, the diet can be raised. There is no definite level, but I suspect for the present I shall incline to values around or slightly below 150 Gm of carbohydrate rather than above it, although some patients tolerate much more. How higher carbohydrate values will work permanently I cannot predict and therefore shall await with interest reports from those clinics where they have been advocated most. It is quite possible that for a few months values may be raised because of the improvement in the treatment of the case, but, having reached that level which corresponds to the ability of the pancreas to utilize carbohydrate in that particular instance, I doubt whether further advances will be made, and I believe that most physicians will find it wise to keep the carbohydrate between the limits of 100 and 200 Gm of carbohydrate and most of the cases at about 150 Gm.

One hundred and fifty grams of carbohydrate is a very simple prescription. Bread, three slices (90 Gm) equivalent to (3 × 18) 54 Gm of carbohydrate, oranges, medium size, three (3 × 15) or 45 Gm of carbohydrate, cereal, one liberal portion, 20 Gm of carbohydrate, 5 per cent vegetables, four portions, 20 Gm of carbohydrate, milk, 4 ounces, 6 Gm of carbohydrate, cream, 4 ounces, 4 Gm of carbohydrate, total 149 Gm of carbohydrate. And, for protein and fat, one egg, a moderate portion of meat or fish at two meals and perhaps bacon for breakfast. Butter in moderate amount, 1 ounce for the day. Omit the bread or the oranges and the diet drops to about 100 Gm and from that point is easily built up again.

For the untreated case one can begin with protamine insulin 10 units before breakfast and advance 10 units daily up to 40, even 50 or 60 units. All the while one watches the diet, adjusting it as necessary from meal to meal to get rid first of all of red and orange tests with Benedict's solution and later of yellow and green tests. I don't like to raise the carbohydrate from the initial value prescribed, from 100 to 150 Gm, until the urine becomes sugar free. I will repeat, the good effects of the protamine insulin may not appear for

several days after the maximum of the protamine insulin has been reached, and indeed the effect may be cumulative, and although with 40 units the urine may contain from 20 to 40 Gm of sugar in twenty-four hours this may entirely disappear a few days later without change in insulin. The patient subsequently may even suffer reactions. Repeatedly this is apt to occur following discharge from the hospital, and unless the greatest pains are taken to warn both physician and patient of this possible eventuality, an embarrassing protamine insulin reaction may occur at home. A reaction arising under these conditions is unfortunate because the patient may become discouraged, whereas he should be encouraged at his gain in tolerance and plan to utilize this in the future.

† Includes one case age not stated

The median dosage for all our patients (657) on protamine insulin alone is 22 units. For those under 20 years of age it is 27 units and for those over 20 years it is 21 units.

Regular insulin can be given simultaneously with the protamine insulin if the latter does not suffice to control the condition. As a rule this would amount to one-half the protamine insulin, but in certain instances it might be the same number of units at the beginning with the hope of reducing it later. In changing patients from regular insulin to protamine insulin I think it is safe to give the accustomed dose of regular insulin and, in addition, the equivalent in protamine insulin for the number of units of regular insulin previously employed for the rest of the day. Six hundred and

DR. ROBERT HELLIG

35 JAN 1922

fifty-seven of my patients use regular insulin and 593 both regular insulin and protamine insulin, but I am in hopes that this number can be reduced, and, in fact, this is taking place.

The median total dosage of the 593 patients using both regular insulin and protamine insulin is 50 units, of which 36 units is the dosage of protamine insulin. For patients under 20 years of age the total dosage is 56

* Includes one case age not stated

units and the protamine insulin 39 units. For those over 20, the total median dosage is 45 units, of which 34 units is protamine insulin.

The total number of units remains essentially the same for all patients taking regular insulin and later changing to protamine insulin. The figures are 25 or 24 units. For those changing from regular insulin to the combined regular insulin and protamine insulin there is an increase in the number of units, namely, from 44 to 50. Whether the patient is under or over 20 years of age, the differences are not great for those on regular insulin alone, but for those with regular insulin and protamine insulin the increase is, for those under 20 years of age, from 47 units of regular insulin to 57 units of regular insulin and protamine insulin. Over 20 years of age the increase is from 42 to 46 units.

The division of carbohydrate between the three meals has been, as formerly, one fifth at breakfast and two fifths at each of the others. If glycosuria persists, carbohydrate is lopped off the meals and given as lunches between meals or on retiring. In 49.2 per cent of 664 patients taking protamine insulin the diet was increased in carbohydrate over that previously consumed, in 36.9 per cent it remained the same, and in 13.9 per cent it was reduced. The greatest number of increases was between 6 and 19 Gm of carbohydrate.

Confusion frequently exists concerning the control of a case. A red test to the well trained diabetic patient is dreadful. But investigation may show that this

was a test representing actually urine voided only during one or two hours. Often these specimens lead to erroneous conclusions, and insulin may be added quite wrongly. Thus a patient may show sugar on rising, but if one secures a fresh specimen half an hour later, that specimen may be sugar free. A second specimen always should be obtained when the urine is tested following the intravenous or subcutaneous injection of dextrose. A second specimen should always be sought if an insulin reaction or coma cannot be diagnosed by a blood sugar test. This simple procedure will save the patient many a needless reaction and may save his life.

During the Naunyn and Allen diabetic eras, 1898-1922, the greatest attention was paid to the carbohydrate and dextrose balances of a diabetic patient, and progress was hailed when these changed from negative to positive. The metabolism of the patient was studied as a whole. Today I see that there is a return to the same method, and just as I have recently graded my cases by their carbohydrate balances I believe all physicians will do it more and not rely so exclusively on single urinary tests and blood sugar estimations. There is no doubt that the physician is having much difficulty in steering his patients between reactions and glycosuria, and therefore a measure of control for an entire day is most helpful.

Local reactions develop with protamine insulin, but these have been growing less frequent and of late so rare that patients seldom call attention to them. There have been several exceptions and, as with regular insulin, I have changed from one product of protamine insulin to another by another manufacturer and with good results. In one man urticaria developed. Local

† Limited to patients for whom complete data before and with protamine are available excludes newly diagnosed patients

reactions with protamine insulin, however, do appear more often and more extensively than with regular insulin. Perhaps it is because so little stress is deliberately laid on them that the number recorded is so small. No instance of an insulin atrophy has come to my attention in any of my patients taking protamine insulin.

Eighty unit strength of protamine insulin acts just as efficiently as 40 unit strength. I have tested preparations of 80 unit strength of two manufacturers and in each instance I can make this statement

unequivocally Furthermore, 80 unit strength of protamine insulin has the advantage that it is less likely to cause indurations in the skin With some patients these are quite disagreeable, although with prolonged use of protamine insulin they eventually disappear It is true that these indurations, or almost inflammatory reactions, may continue for from two to three weeks I have never encountered in a patient an abscess which I thought was surely due to an injection of protamine insulin, even though some of the reactions are of an angry appearance In one patient taking both kinds of insulin and also other subcutaneous injections, an abscess developed but I never felt satisfied as to its true origin

Regular insulin and the protamine insulin should be given separately in order to secure the full effect If the same syringe is employed, the regular insulin should be injected first and then the protamine insulin may be drawn into the syringe and injected If the reverse plan is followed, the residue of protamine insulin on the inner surface of the syringe would be enough to convert the regular insulin into protamine insulin, to a greater or less extent However, some clinicians have given a mixture of the two in the same syringe and have felt that the effect of regular insulin could be demonstrated in the patient as well as the protamine insulin Such a result would be welcome, but it hardly seems consistent with the chemistry of regular insulin and protamine insulin that this could occur, at least with any constant ratio of effect, and when I have tried it it has not worked satisfactorily

The experimental period in the use of protamine insulin has not passed Recently from Dr Himsworth¹ of London I learned that he had excellent results from administering protamine insulin at 11 p m This appears to bring it about that the food is far better utilized in the morning of the next day than if the protamine insulin were given before breakfast I have had insufficient experience to express an opinion on this point

The decreasing size of the liver under protamine insulin medication first described by Janssen of the Hagedorn clinic has been confirmed with my patients In fact, I am told by my colleagues Dr White and Dr Marble that protamine insulin has proved more efficacious in bringing this about than any other treatment that they have used in their studies of the enlarged livers of the forty children, more or less, whom they have investigated

Change in weight is characteristic from the use of protamine insulin Recently, a report from the Scripps Metabolic Laboratory showed that protamine insulin is more efficacious in producing a gain in weight in nondiabetic animals than regular insulin²

The Mayo Clinic has shown that protein catabolism is reduced during the night when patients take protamine insulin instead of regular insulin

With protamine insulin the diabetes is undoubtedly better controlled and perhaps a little better controlled than one should attempt Particularly with a certain group of patients, who have lived for a decade, more or less, with blood sugars quite a little above the normal standard, it is a question as to how long it will take for them to become accustomed to a normal blood sugar, and certainly it is a question as to how seriously one should insist on bringing this about These are

factors that only time can settle They are conditions that occur only with patients who have been trained with regular insulin and so are not encountered in a patient who begins his treatment with protamine insulin

A quite unanticipated benefit from the introduction and daily use of protamine insulin has been an alteration in the attitude of diabetic patients toward their disease Instead of being neglectful and indifferent as they often were to their tests, resisting efforts to keep them more nearly sugar free, they now watch their reports very closely and expect and demand that the physician produce his predicted good results This is a healthy sign It is certainly desirable for us medical men to be challenged to improve our treatment The behavior of these patients reminds one of the stimulus Dr Keen said he felt from having a pack of young surgical hounds at his heels

The goal of diabetic treatment is by no means yet reached It is safe to predict that new methods of therapy will appear at increasingly frequent intervals One almost hopes that they will not come so rapidly that we fail to discover all the advantages of the measures which we now have

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT HOWARD A CARTER Secretary

FISCHERQUARTZ MODEL NO 27 COLD MERCURY ARC LAMP ACCEPTABLE

Manufacturer The Fischer Corporation Glendale, Calif

This is a small mercury glow lamp designed solely for local applications, a dermatologist model The burner is mounted in a bakelite handle with chromed brass fittings and has an aperture opening $2\frac{1}{2}$ inches in diameter The tripod and control box are finished with black hard metal and chromium An automatic timer comes with the equipment The burner can be used with the same stand and controls employed for other Fischerquartz lamps It can be operated only on an alternating current circuit It appears to be well constructed

The burner is a mercury vapor one of low pressure variety, low amperage, high potential, glow discharge similar to the well known Geissler tube The tubing is of transparent quartz, highly evacuated, and contains rare inert gases and a few drops of mercury The power consumed is small and consequently there is no great rise in temperature of the burner

The radiation characteristics are essentially the same as those of other Fischerquartz lamps that have been previously accepted by the Council¹ The source is much smaller since the unit is designed for local applications Of the total radiation of all wavelengths less than and including the line of 3130 angstroms, more than 95 per cent is contained in the resonance emission line of mercury vapor at 2537 angstroms

The unit was placed in a clinic acceptable to the Council for investigation Little heat developed Following a thirty second exposure with the metal shield in contact with the skin, a faint erythema developed in about six hours and disappeared in twenty-four hours Exposure of one minute produced a moderate erythema and of two minutes caused an intensive erythema

¹ Fischerquartz Cold Ultraviolet Lamps Acceptable J A M A 102 1620 (Nov 24) 1930 Fischerquartz Ultraviolet Lamp Model No 77 Acceptable ibid 106 1806 (May 23) 1936

At a distance of 6 inches, four minutes was required to cause a faint erythema. When a Fischerquartz large lamp was used for thirty seconds at the same distance (6 inches), a similar erythema was produced.

These tests substantiated the claims made for it by the firm. The Council on Physical Therapy voted to include the Fischer-quartz Dermatologist Model 27 Cold Mercury Arc Lamp in its list of accepted devices.

tration of serum is on or before the twelfth day of tularemia. When this was done, significant reductions in all the measurable phases of the disease were obtained.

[End of Dr Foshay's data]

The Council considered the foregoing data, and, while finding nothing definitely to criticize, concluded that corroborative data by other investigators are needed before the product can be accepted for inclusion in New and Nonofficial Remedies. The Council therefore voted to postpone consideration of Anti-tularemia Serum-Mulford (Sharp & Dohme, Inc) to await development of further data and authorized publication of this report.

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH Secretary

PENTOBARBITAL SODIUM-ABBOTT
(NEMBUTAL) OMITTED
FROM N N R

Before specific consideration of the brand of pentobarbital sodium, which the Abbott Laboratories has decided to market as "Nembutal" it might be well to consider the rationale of the Council's rules concerning the recognition of proprietary names.

THE RIGHT OF DISCOVERY

A coined, protected, proprietary name confers a monopoly, which, if it is effective, limits the rights of the public, or, if it is ineffective, causes confusion by creating artificial distinctions where none exist in fact. It has happened in the past that the same identical substance was prescribed by different names twice or oftener in a single prescription. Such confusion is against the interest of public, of patient and of physician, and so also are the limitations that monopoly imposes unless this is so clearly justified that it would be unjust to refuse it. The only ground on which this right of monopoly is recognized automatically by the Council is that of the discovery of a new substance. This is recognized for the same reason that underlies the granting of patent monopoly, namely, to encourage the development of invention for the benefits which the public may derive from it, and also because a discovery is naturally the property of the discoverer. There are, however, some questions as to what may be considered a "new substance" in this sense. This involves originality as well as priority. For instance, the formation of a salt by simply putting together a known acid and a known base would not constitute a discovery, even if no one happened to have put the two together before. In principle this is no more new than adding two numbers in elementary arithmetic, and the sum is scarcely more of a discovery in the one case than in the other. The substitution of different radicals of a homologous series is equally obvious, and there are many similar cases, which involve nothing new, nothing which any one versed in that branch of chemistry would not have foreseen and worked out, without special difficulty, had he been so inclined. Such obvious, perfectly predictable preparations, then, are not entitled to the status of "discovery," unless their preparation involves some unexpected or baffling difficulties the solution of which may constitute justifiable basis for the claim that the products are new preparations, this would not be automatic but would require the evaluation of the circumstances.

FINDING OF NEW USES FOR AN OLD DRUG

The Council may also accept proprietary names for the discovery of important therapeutic value in previously known substances that have not been used in medicine, or when new uses or actions of exceptional novelty and importance are discovered for substances previously used in medicine but which had become practically obsolete, but if the substance itself is not a discovery, the acceptance of the proprietary name is not automatic but is accorded only by special action if it is quite clearly in the interest of public welfare. It would be obviously undesirable to extend this privilege to the discovery of new therapeutic properties in substances that are in active use in medicine, for instance, to call antimony potassium tartrate "tartar emetic" when it is used as an emetic and something

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT
PAUL NICHOLAS LEECH Secretary

ANTITULAREMIC SERUM-MULFORD

Sharp & Dohme, Inc, presented for the Council's consideration Antitularemic Serum-Mulford prepared by immunizing horses by injecting cultures of B tularensis isolated from human cases of tularemia. While the Council was familiar with the favorable reports of Dr Lee Foshay of the College of Medicine, University of Cincinnati, on the use of experimental batches of serum, the firm was asked to present evidence that the commercial product is useful in treating human tularemia. The firm, in turn, referred the Council to Dr Foshay.

On request Dr Foshay kindly submitted comparative data obtained from 334 untreated cases of tularemia and 481 serum treated patients. He gave a separate analysis of 133 patients (included in the treated group) who received Antitularemic Serum on or before the twelfth day of the disease.

Comparative Data from Tularemia Patients

Duration of	(Means unless indicated otherwise)		
	Untreated N = 334	All Treated N = 481	Treated Twelfth Day or Earlier N = 133
Disease (mos)	4 10 ± 0 11	2 77 ± 0 05	2 32 ± 0 08
Disability (mos)	3 11 ± 0 14	2 13 ± 0 04	1 62 ± 0 07
Adenopathies (mos)	3 61 ± 0 08	2 32 ± 0 05	2 02 ± 0 08
Serum recovery interval (days)		1 78 ± 0 04	1 99 ± 0 08
Fever (days)	27 92 ± 0 84	25 69 ± 0 53	20 19 ± 0 76
Primary lesions (days)	39 12 ± 2 14	31 59 ± 0 54	26 53 ± 0 84
Hospitalization (days)	30 51 ± 1 99	22 76 ± 0 55	21 17 ± 0 90
Suppurative adenitis incidence	54 0%	42 0%	37 0%
Exanthem incidence	No data	21 4%	
Initial serum given average day of disease		26 8	7 5
Mean (days)		26 34 ± 0 72	7 97 ± 0 18
Mode (days)		14 84	6 79
Mortality rate	5 8%	1 9%	3 0%

By way of interpretation of the foregoing data, Dr Foshay presented the following table.

Significance of the Obtained Differences Between the Means

Duration of	Control Cases Compared With			
	All Treated Cases N = 481		Early Treated Cases N = 133	
	Difference	P E Diff	Difference	P E Diff
Disease	1 33 ± 0 12	10 99	1 78 ± 0 11	16 01
Adenopathy	1 29 ± 0 10	13 56	1 59 ± 0 17	13 48
Disability	0 98 ± 0 15	6 61	1 49 ± 0 12	12 85
Fever	2 23 ± 0 99	2 24	7 73 ± 1 13	6 82
Primary lesion	7 53 ± 2 21	3 41	12 59 ± 2 30	5 47
Hospitalization	7 75 ± 2 07	3 75	9 34 ± 2 18	4 28

The constants underscored are statistically significant. The odds against the least of these deviations occurring by chance alone are greater than 150 to 1. The optimal time for adminis-

else when it is used against bilharzia, and something else again when it is used against granuloma inguinale. It would also be undesirable to give proprietary names to familiar substances not in current use in scientific medicine such as egg shells or brick dust. Again, the therapeutic discovery must involve some valuable property that is essentially new, something that was not generally predictable, although it may have been foreseen by the discoverer, working out a definite theory. For instance, after it had been shown that antimony potassium tartrate is effective against bilharzia, it would not be a "discovery" to find that antimony sodium tartrate is effective against this parasite or that it is somewhat safer intravenously, since this is a common property of sodium salts.

OVERCOMING OF DIFFICULTIES TO MAKE A DRUG AVAILABLE

Another reason for which a proprietary name may be granted is that of priority in making a substance available to the public. This also is not automatic. It is not usually granted on the basis of priority alone but must involve some definite and adequate merit, such as the conquest of special difficulties, which would mean that the substance would probably not have been accessible, at least for some time, without the ingenuity of the introducer. For instance, the supplying of a purer article than the common market affords would be considered adequate only if the methods of purification themselves constituted essential discoveries. If it involves merely the application of known obvious methods, there would be nothing new on which to base rights of discovery. In practice, the merit of introduction is rarely found sufficient to justify the acceptance of a proprietary name.

DEFINITION OF PRIORITY *

Finally comes the question of what constitutes priority. In most cases this is fairly plain, in others it is quite complicated. The scientific world has one set of standards the Patent Office has another, absolutely different. Both are necessarily arbitrary, and neither fits entirely the problems that face the Council. The rules of the Patent Office are framed for disposing of a vast number of inventions of all kinds—and then letting the contestants fight it out in a succession of courts. Nor do the Patent Office rules take account of the special status and conditions of monopoly in medicines. Not infrequently patents have been granted which to enlightened medical opinion appear plainly contrary to the interest of the health of the public. The scientific rules of priority, on the other hand, were not framed with a thought of securing monopoly of any kind but rather for the orderly arrangement of the steps which have led to a scientific discovery and which frequently apportion the credit among a number of independent investigators. Scientific discoveries are rarely if ever "independent", for they could not have been made without the use of the vast body of scientific knowledge that entered into the training of the investigator, and of a complex and extensive ramification of the discoveries of other investigators, which "led up" to the final discovery. These conditions greatly circumscribe the "natural right" to a monopoly in a discovery in the making of which so many others have shared, and they emphasize the justice of conceding such monopoly only if it appears clearly in the public interest. This means that every case which presents unusual features must be weighed by itself in the balance of the public welfare. If the case is not clear, it is wiser to withhold the monopoly, for it is always much easier to concede it later, if that becomes indicated, than to withdraw it after vested interests have become established in it.

THE CASE AGAINST "NEMBUTAL"

The case of pentobarbital sodium viewed in the light of these principles, appears as follows:

The Abbott Laboratories profess themselves entitled to the commercial monopoly of a proprietary name for this substance on the basis of discovery. They concede that they were not the discoverers of the free acid, but they contend that they discovered the novel therapeutic qualities and were the first to

publish these. These qualities are nothing new in kind, for they are the same as those known for other similar barbiturates, the chief difference is that the action is briefer than that of some others, but this again is not fundamentally new, since it is merely a step in the gradation of action of the numerous barbiturate derivatives. It would therefore be questionable whether the discovery was such as the Council would consider a clear title to a commercial monopoly. Nevertheless, as the substance appeared to fill a therapeutic need, the Council would have been inclined at least seriously to consider extending this privilege to the limited discovery. However, it happened that before the discovery was published it had also been made independently by another firm, Eli Lilly & Co., and the only discovery of anything at all novel, the brief duration of action and its importance did not originate from either of these firms but in the University of Wisconsin¹. It is true that the Abbott Laboratories published their work shortly before Eli Lilly & Co. and thus secured priority in that sense. It does not appear clear, however, that the public interest would be served by basing a monopoly merely on the date of publication, for this would give all the advantage to the one who rushed into print at the first suggestion of immature and uncontrolled results and would discourage the careful, painstaking investigation that should precede even the first announcement of a discovery.

It may be added that the pharmacologic part of the Abbott publication was confined to the relation of the toxic and "effective" dose for hypodermic administration in rats which the Wisconsin investigators characterized as unimportant, and that no data were published by which the competence of the conclusions may be judged. The only detailed investigation published by either firm is the second communication from the Lilly Laboratories, published about a year later—too late for any credit of discovery.

The Abbott Laboratories contend that they were more active in promoting experimentation, laboratory and clinical by others, and that most of these used the Abbott product. Both statements may be granted, but these activities constitute promotion, not discovery.

In view of these considerations, it appeared to the Council as definitely against the public interest to concede to the Abbott Laboratories a monopolistic name for this product, which they did not invent, the chief actions of which were not new and of which they had not been the sole investigators. The Council therefore gave to the substance the nonmonopolistic name "Pentobarbital," based on its chemical characteristics, but in order to allow the Abbott Laboratories ample time for adjustment, it extended to them for a year the privilege of using the name "Nembutal," which they had copyrighted, as a synonym. The firm accepted this condition under protest. Later the Council extended the period for six months additional, but now that the period has expired, the firm informs the Council that it will return to the use of the copyrighted name. Under the circumstances, the Council can only withdraw its acceptance of the Abbott Laboratories' brand of pentobarbital sodium, while continuing its acceptance of the Lilly brand. At the same time it feels that the Abbott Laboratories once having acceded to the conditions of the acceptance of their brand and secured the benefits of its introduction to the profession under these conditions, should in good faith have continued to abide by them.

1 The Wisconsin workers (Tatum et al.) made no mention of any aid from a manufacturer in their original paper but two years later in their more extensive paper they do add a footnote saying: "Substantial aid in this investigation was received from the Abbott Laboratories. This acknowledgment comes somewhat late to be considered as a basis of priority but in any case it does not materially alter the situation a grant does not transfer the discovery to the manufacturers at least unless there was a definite previous agreement to this effect and no information along this line has been submitted. The paper does not acknowledge any indebtedness for ideas to the contrary it again depreciates the value of the therapeutic index which was the sole pharmacologic contribution of Volwiler and Tatum of the Abbott Laboratories."

In a communication from Dr. Tatum he states in part: "The comparative idea [calibration of barbiturates on the basis of duration of action] developed in our minds after we had examined nembutal carefully in comparison to other barbiturates. Of course other features such as toxicity etc. were determined. Then on looking at the several properties the duration factor began to appeal to us as a practical differential feature."

CAUSALIN (CAUSYTH) NOT ACCEPTABLE FOR N N R

"Causalin" is another name for Causyth, which was exploited several years ago in Austria as a treatment for arthritis. A number of recent inquiries from American physicians about Causalin prompted a review of the present claims for the product. The status of Causalin is about the same as that of Causyth reported in *THE JOURNAL*, March 1, 1930.¹ At that time a referee, who reviewed most of the reports on Causyth in German medical literature, held the evidence unsatisfactory and uncritical and the product therapeutically worthless and ineffective, except for possible shock effects which might be dangerous. There were widespread reports in this country that the public health ministry of Austria controlled the manufacture of Causyth and required its use in treatment of arthritis by government physicians. However, there was no indication of this being the case in the advertising or in physicians' reports on the product. Today the product is being exploited as Causalin in this country by the Amfre Drug Co., Inc., 31 East Twenty-Seventh Street, New York City, without reference to Austrian health authorities. Presumably the product is manufactured abroad and distributed by this agency in this country.

While it is not expressly claimed by the distributor that Causalin is a chemical compound, the implication is clear in the advertising circulars, which state that the chemical name for it is "aminodimethylpyrazolon-quinoline-sulphonate." In this connection, Nilsson's² opinion of the product is of more than passing interest. "Causyth (Causalin) is an Austrian preparation for antirheumatic treatment consisting of about equal molecular parts of pyramidon and 8-hydroxyquinoline-5-sulfonic acid. It is in no sense a chemical compound but a purely mechanical mixture and hence is misbranded by being called 'Cyclohexatrienpyridinsulfonsaures Pyrazolonderivat.'" Apparently the labeling of the product is in conflict with drug regulations in Germany. Clearly, there is nothing original about the product, consisting as it does of the well known official drug aminopyrine (U. S. P.) and the active chemical group hydroxyquinoline or chimofon (U. S. P.), which is an amebicide and a mild wound antiseptic. Quinoline is also an important chemical group in quinine (U. S. P.) and cinchophen (N. F.). Accordingly, such statements as the following in the advertising literature appear misleading: "Causalin (aminodimethylpyrazolon-quinoline-sulphonate) contains no cinchophen and no cinchophen derivatives." Nor is there any justification for obscuring the presence of aminopyrine by using only a long chemical name in place of a more generally understood and informative name, for the medical profession. Furthermore, the medicinal value claimed for Causalin is, of course, the same as for aminopyrine, except for therapeutic exaggerations and omissions of warning of possible toxicity and side actions.

Since aminopyrine, or its mother substance antipyrine, is well known to produce analgesic and antipyretic actions, it is possible, if not probable, that Causalin can afford relief from pain and fever in arthritic and rheumatic states. Granted that a diagnosis would justify the use of an analgesic like aminopyrine, this could give only temporary relief at best. However, the physician is told that Causalin can do more, to wit: "Because Causalin, experimentally, clinically and practically has shown that it exercises material as well as symptomatic control over arthritis."

"It further seems to exert what may be called the ideal therapeutic influence, in that it confuses itself to restoration of normal mutual relations between the endocrine and nervous systems." Causalin exerts a regulative action.

"Causalin acts upon the cause of the disease" (Referee's italics). These statements imply some mysteriously favorable influence of Causalin on causal connections between the endocrine glands, nervous system and arthritis. Really, however, this is an empty hypothesis, as there is no reason to believe that the composition of Causalin could promote regulation or integration of endocrine and nervous functions. Causalin is in no sense "a marked therapeutic

contribution" to, or "a true advance" in, scientific medicine, as new and unheard of effects could not very well result from the well known.

It is claimed in the advertising that "published clinical reports on Causalin show that it effectively relieves symptoms in all types of arthritis." The older reports on Causyth were found to be valueless as to acceptable evidence,³ and the only available recent report is that by Robert Bernhard, M.D., under the title "A New Treatment of Arthritis."³ This report discusses theoretical considerations of arthritis, clinical claims of others concerning actions of Causalin and recapitulates case histories of eleven patients treated with Causalin by the author. As for temporary relief from pain, the evidence adduced by this author is not decisive either for or against. Eight of the eleven treated patients were admittedly not completely or permanently relieved of pain and other symptoms. On the whole, the author's conclusions are consistent with the character of the evidence, not exactly laudatory or condemnatory of the product, although he inclines to credit Causalin with some "definite advantages." It could not be otherwise, because any analgesic may give temporary relief in arthritis. The author has no evidence to justify his conclusion that "liver function is apparently unaffected." But he gives one warning, which is not given in the advertising literature, and that is "*Conclusion 5 Contraindications. Since this preparation shows a tendency to increase blood pressure, it should not be prescribed in cases where high blood pressure already exists*" (Referee's italics). The reasons or evidence for this side action are not given, but it may be due to the aminopyrine, which is known to possess a central excitant action. It is this phase of the propaganda for Causalin, a harping on harmlessness and high tolerance, which is most reprehensible, because of a callous indifference to possible serious consequences of indiscriminate medication with aminopyrine.

There is not a single mention or even a warning anywhere in the available advertising literature issued by the distributor of the possible occurrence of agranulocytosis, especially in sensitive persons. On the contrary, the following statements indicate a general denial of possible trouble from the use of this product: "In chronic cases, Causalin may be taken over long periods of time without harmful effects." "Causalin is non habit forming." "Causalin is harmless. It may be taken indefinitely." "Does not cause liver complications." "Does not depress the heart." "No gastric disturbance." "No danger of overdose." "without any by-symptoms." "No dietary restrictions and requires no synergistic aid." "Causalin acts quickly, surely and safely." "And this is accomplished without any by-symptoms." "Causalin is available as an ethical product—Your prescriptions may be filled thru any reliable pharmacy. Any pharmacist may obtain Causalin through his regular wholesaler or directly from us." These statements illustrate all the elements of quackery without a conscience or the slightest responsibility toward the physician and the patient.

A conscientious physician would not, in this day, of course, accept the manufacturer's advice if he realized that Causalin was essentially aminopyrine. But Causalin is being dispensed in drug stores, and refilling of prescriptions is encouraged without warning of physicians and pharmacists of the dangers of such medication, contrary to repeated warnings in the medical press. Such callous indifference to public health and welfare and disregard of the physician's liability justifies the severest condemnation and public exposure of the facts. There is nothing in any of the clinical reports, even the recent one by Bernhard, to indicate the slightest concern over what medication with Causalin might do to the blood, for instance there are no observations or records of blood counts, hemoglobin, sulf hemoglobin or anemia, whereas today an oversight of thorough and continued blood examinations in patients medicated with aminopyrine or its derivatives or related products is an incriminating omission of the first order. Equally or more reprehensible is a neglect of the far simpler procedure of giving a warning of the possible occurrence of agranulocytosis.

As regards the following claim in the distributor's advertising literature under the heading "The Non toxicity of Causalin,"

¹ Causyth. Queries and Minor Notes. *J. A. M. A.* 94:656 (March 1) 1930.
² Nilsson H. *Pharm. Presse. Wiss. prakt. Heft* p. 47. 1932.

³ Bernhard Robert. *M. World* 54:378. 1936.

which purports to give assurance based on experimental evidence, it is essentially meaningless and valueless and certainly so as regards such a side action as agranulocytosis. "In one of their series of experiments, Guenther, Magree and Wagner took rabbits, weighing 2 kilos, and gave them each 10 tablets Causalin (75 grains) at one time. They found that the rabbits stood this dosage without secondary effects. A stimulating effect on the gall was further noted. In another series, dogs, weighing 6 kilos, had 15 grains Causalin injected subcutaneously. No toxicity or other unwarranted or harmful symptoms were observed." Conspicuous as these statements are by their noninformative character, physicians know that, so far as such blood changes as are concerned in agranulocytosis, the experimental results with aminopyrine and related products have been equivocal or negative in the hands of qualified investigators.⁴ Therefore such results with lower animals are not transferable to man, who is more sensitive and reactive to this class of products. In fact results on animals may be quite misleading and produce a false sense of security, as they may indicate almost the opposite of agranulocytosis. However, the clinical experiment with aminopyrine has been made and the answer is clearly caution in medication, if anything. Since an attitude of caution does not in any sense distinguish the exploiters of Causalin, which after all is largely a means of indiscriminate distribution of aminopyrine to the public, the medical profession owes a duty to the public and to itself to stop the use of this product.

The claims for Causalin (Causyth) are exaggerated, misleading and unwarranted, and the product has no place in the therapeutic armamentarium of responsible, qualified physicians. The exploiters of the product are to be censured for omissions of warning concerning its dangerous toxic potentialities, for obscuring the essential composition of the product by using an unnecessarily long and unfamiliar chemical name for the well known drug aminopyrine, and for using the noninformative name Causalin. There is no good reason to believe that the claimed composition of Causalin entitles it to be considered a chemical compound as indicated in the advertising; apparently it is a mixture, without originality or rationality. Causalin is to be condemned as an unsafe and dangerous product, the exploitation of which is against the interests of the public and the medical profession.

The Council declared Causalin (Causyth) not acceptable for N N R. for the reasons given in the foregoing report.

DOSAGE OF PREPARATIONS CONTAINING VITAMINS A AND D

The Council has fixed the dosage of cod liver oil-N N R. for infants at two teaspoonfuls daily. This involves a vitamin A dosage of 6,250 units and a vitamin D dosage of 625 units. The dosage statement is based on vitamin D requirements for the prevention of rickets and probably provides an excess of vitamin A. While there are no data on which the vitamin D requirements of growing children or adults could be based, the indications are that the vitamin D requirements for these groups is less than for infants, so that two teaspoonfuls of cod liver oil daily would in all probability supply a sufficient intake. There are very few data bearing on the vitamin A requirements of man other than infants. From evidence obtained on experimental animals, it appears that the requirement increases to some degree with increase in size of the animal. The Council therefore felt that the recommended dose of cod liver oil for adults should be two teaspoonfuls daily and that this amount would probably meet the minimum requirements for both vitamins A and D.

In view of the foregoing the Council held that the recommended dosages for capsule and tablet preparations of vitamins A and/or D should not be less than the minimum dosage for infants and adults equivalent to two teaspoonfuls of cod liver oil-U S P (minimum strength).

⁴ Hanzlik, P. J. Agranulocytosis. A Critical Review of Causes and Treatment. Historical and General (Report of Council on Dental Therapeutics). J. Am. Dent. A. 22: 487 (March) 1935. Amidopyrine and Granulocytopenia. Report of Council on Pharmacy and Chemistry. J. A. M. A. 102: 2183 (June 30) 1934.

The Council voted the requirement (1) that the dosages of accepted preparations of vitamins A and/or D provide at least the equivalent in these vitamins of two teaspoonfuls of cod liver oil but not more than 10,000 units of vitamin A and 1000 units of vitamin D, and (2) that dosage statements on labels and in advertising should be accompanied by the phrase "or as prescribed by your physician."

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMPLEMENTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

RIBOFLAVIN—6,7-dimethyl-9-[d, l'-ribityl]-isoalloxazin— $C_{17}H_{20}N_4O_6$ —Formerly called Lactoflavin, Vitamin B₂, and Vitamin G—Riboflavin is the heat stable factor of the vitamin B complex.

Actions and Uses—The significance of riboflavin in human nutrition is at present unknown. No therapeutic claims are advanced for riboflavin. It is accepted for experimental purposes only.

Dosage—For human beings, from 2 to 3 mg seems to be the average dosage. The requirement of riboflavin during pregnancy and lactation is higher. No side effects have been noticed in relatively large doses.

Riboflavin occurs in clusters of fine orange-yellow needles. It melts with decomposition at 280°C (Kofler micro melting point apparatus; rate of heating 5°C per minute starting at 250°C). It is slightly soluble in water (2.5 parts in 100,000) at 25°C, soluble in alcohol, cyclohexanol, amylacetate, insoluble in ether, chloroform, acetone and benzene. The greenish yellow water solution has an intense yellow-green fluorescence which vanishes on the addition of alkali or acid. The optimum of the fluorescence is between pH 3 and 9. The iso electric point is at pH 6. The optical activity of a 0.1 to 0.5 per cent solution in 0.05 normal sodium hydroxide is between $[\alpha]_D^{25} = -80$ and -100° . The oxidation and reduction potential is at pH 7 = -0.20 volt. The extinction coefficient of a 0.005 per cent solution of pure riboflavin in water is $E = 1.45$. The spectrum shows a band in the visible with a maximum at 445 millimicrons, one in the near and two in the far ultraviolet (372, 269, 225 millimicrons).

Dissolve 0.025 Gm of riboflavin in 6 cc of absolute pyridine after cooling, add 6 cc of freshly distilled acetic anhydride. Heat the solution for ten minutes, cool and dilute with 10 cc of chloroform, add 5 cc of diluted hydrochloric acid (1:5) and wash the layer of chloroform several times with water, transfer the chloroform layer to a beaker and evaporate, dissolve the residue in 15 cc of hot, diluted acetic acid (1:2). After two days crystallization is complete. Recrystallize the product twice from water, the melting point of the dried material (Kofler micro melting point apparatus) is 238°C. Weigh out accurately about 5 micrograms of the dried penta acetate, determine the nitrogen content according to the Pregl micro-Dumas method, the nitrogen content of the penta acetate is not more than 10.6 per cent or less than 10 per cent; micro ash determination on the penta acetate of riboflavin is less than 0.05 per cent.

Saponification of the penta acetate: triturate 0.01 Gm of penta acetate with 5 cc of 0.1 normal sodium hydroxide. Extract the unreacted material with chloroform and acidify with 5 cc of acetic acid. Crystallization of the original riboflavin is completed in two days. The melting point is 280°C.

Accurately weigh 5 mg of riboflavin in a microplatinum boat and combust the product in a Pregl micro muffle in a stream of oxygen, the amount of oxide ash is not more than 0.2 per cent. The U S P VI test for chloride, lead and arsenic should be negative.

Weigh out accurately about 5 mg of riboflavin and determine nitrogen with the Pregl micro-Dumas apparatus, the nitrogen content is not more than 15.2 and not less than 14.5 per cent, theory 14.88 per cent.

Dissolve approximately 0.03 Gm of riboflavin weighed accurately in 0.05 normal sodium hydroxide at 25°C to make 12.5 cc of solution, determine the optical activity in accordance with the U S P VI directions, the specific rotation $[\alpha]_D^{25}$ is -90° .

For quantitative determination of riboflavin in solutions, fluorescence analysis is used (Euler, H. V. and Adler, E. *Ztschr. f. physiol. Chem.* 223: 108, 1934).

Riboflavin Synthetic "Roche"—A brand of riboflavin-N N R.

Manufactured by F. Hoffmann-LaRoche & Co., Basle, Switzerland (Hoffmann-LaRoche, Inc., Nutley, N. J., distributor). No U S patents or trademark.

Riboflavin Roche Ampules 2 cc. Each ampule contains 2 cc of a solution containing 0.05 per cent (1 mg.) of riboflavin.

GOLD SODIUM THIOSULFATE-ABBOTT (See New and Nonofficial Remedies 1937, p. 239).

The following dosage forms have been accepted:

Ampules Gold Sodium Thiosulfate Abbott 0.025 Gm
Ampules Gold Sodium Thiosulfate Abbott 0.5 Gm

THE SIDE ACTIONS OF BARBITALS

Barbituric acid and the various compounds derived from it by alteration of the molecule are now widely used. Extensive employment by qualified practitioners and also by the public has grown to proportions that indicate lack of knowledge of the side actions of these drugs. Even more blameworthy is the practice of introducing new and more potent barbitals without reliable investigation of their pharmacologic actions.

Koppanyi and his co-workers¹ at Georgetown University School of Medicine have extensively investigated the side actions of these products. More recently Hanzlik² of the department of pharmacology at Stanford University School of Medicine has summarized them. The recent report of the Council on Pharmacy and Chemistry on evipal sodium³ points out the apparent lack of careful pharmacologic study before the introduction of such products.

Hanzlik indicates three experiments which illustrate depression and paralysis of peripheral neuromuscular elements in the autonomic system caused by amytal, one of the highly active barbitals, which has been promoted for intravenous analgesia or anesthesia. The following chain of evidence justifies the conclusion that ganglionic paralysis or synaptic block in the cardiac vagi may follow the intravenous or intraperitoneal administration of amytal, an action paralleled commonly by such poisons as nicotine and lobeline and sometimes by choline depressor or collapse action (fall of blood pressure), paralysis of vagus control of the heart without loss of function in the peripheral receptive mechanism (ineffective vagus stimulation, fall of blood pressure and bradycardia from choline and pilocarpine), absence of central and peripheral vasomotor paralysis (recovery of blood pressure, and pressor action of epinephrine, positive), cardiac depression

suggested by bradycardia or tachycardia, with constant loss of vagus control, reflex cardiac slowing improbable (ineffective peripheral vagus stimulation). The ganglionic paralysis blocks the transmission of both efferent and afferent impulses in the cardiac vagi, and in case blockage extends to other branches of the vagi and parasympathetic nerves in general, this action of barbitals interferes with visceral reflexes, some of which are protective, such as vomiting and coughing. On the other hand the ganglionic paralysis, together with the central depression of a barbitol, would make an effective combination for controlling asthmatic attacks of reflex origin, a point that is worthy of further investigation and that again illustrates the value of detailed pharmacologic consideration.

All the functional elements in a strip of excised rabbit intestine are included in the depression the muscles perhaps more than the nerves. The concentrations of amytal used for demonstrating these depressant actions were higher than those attainable after oral administration. However, the moderate depressions of the low concentrations indicate effects of anesthetic doses of amytal given intravenously, and those of higher concentrations of repeated and toxic injections. These depressant effects have been noted previously on the intact gastro-intestinal tract.⁴

Other side actions were recorded, such as gastro-intestinal flaccidity and reduced peristalsis, decreased intestinal absorption of dextrose, decreased consumption of sugar by skeletal muscles, decreased urine secretion, alarming restlessness, paresis of the tongue, cyanosis and asphyxia, skin rashes, depression of the spinal cord and reflexes, blood destruction and anemia with intravenous anesthetic doses of evipal, a much exploited barbitol at the present time,⁵ increased blood sedimentation and reduced cell volume with slow return to normal after a number of barbitals and evipal, and very marked reduction of urine output in nephritis, to mention only a few. Many of these actions were obtained with doses or concentrations of therapeutic (anesthetic) range.

The foregoing side actions are particularly important in view of the decreased urinary secretion and the change in the absorption of dextrose, since it is known that diuresis and absorption of dextrose are effective antidotes in barbitol poisoning.⁶ The use of ammonium chloride, another effective antidote, might be similarly

rendered inefficient. These side actions again illustrate the point emphasized by the Council on Pharmacy and Chemistry⁷ and the Council on Dental Therapeutics⁸ against the dangers of intravenous administration of barbitals in unskilled hands.

All in all, these side actions emphasize that all the barbitals cause widespread depression or paralysis of living tissues in varying degrees and that there is no such thing as a nontoxic sedative or anesthetic that may be used with impunity. Some of the side actions might easily obscure or confuse a diagnosis and affect a patient's recovery from a disease in which the barbitol was exhibited merely as a symptomatic or palliative measure. The general condition of the patient should always be kept in mind when barbitals are administered.

A number of state legislatures have passed or are in the process of passing measures limiting the sale of barbitals to prescriptions signed by physicians, dentists or veterinarians. Even better than legislation in this respect is an education of barbitol users to the attending dangers of these compounds. Like most drugs, they are two-edged swords, useful in the hands of those competent to administer them, dangerous in the hands of the incompetent.

Soma Weiss⁹ pointed out some of these in one of the clinical lectures given at Kansas City. He emphasized, as did the Council on Pharmacy and Chemistry, that additional special knowledge, bearing particularly on the pharmacologic characteristics of various hypnotics and on the clinical evaluation of the patient, is essential

NO SUNSHINE IN SOAP

During the past year certain brands of soap have been flamboyantly exploited for their vitamin D content, one for the "filtered sunshine" in its lather. The latter product was introduced to the public with double page spreads in national magazines under the caption "The Dawn of a Great Beauty Discovery." In subsequent advertisements a picture of a nude but decorously posed model entering what appears to be a private outdoor pool on a sunshiny day calls attention to such claims as

"Your skin readily soaks up [the] 'Filtered Sunshine' element—the Vitamin D ingredient—from rich creamy lather as you wash and bathe. This has positive proof in the records of important scientific tests."

There is evidence that irradiated ergosterol may be absorbed through the skin of rats. This evidence has been an excuse for adding vitamins to various cosmetic preparations. H. Stanley Redgrove, writing in the *Pharmaceutical Journal*, London, April 17, has noted

"Many emphatic statements as to their cosmetic utility are to be found in trade and technical literature, but, apart from work demonstrating the utility of cod-liver oil and allied products in facilitating the healing of wounds and burns, one seeks in vain for detailed reports of adequately controlled experiments."

Redgrove points out that the real question at issue is not the ability of the skin to absorb these substances but "whether when so absorbed the vitamins exercise any beneficial action on the skin—in short, whether they are of any cosmetic value." Even if it is established that vitamin D exercises any beneficial action on the skin it still must be proved that it has a beautifying effect. As a matter of fact, there has been some recent evidence which indicates that the alleged beneficial effects mentioned by Redgrove as resulting from the use of cod liver oil in the promotion of healing of wounds and burns were probably due to some other factor than the vitamin D content of the oil.

Other trade journals are skeptical of the usefulness of vitamin cosmetic preparations. Thus, A. L. Bacharach, discussing the flimsiness of the evidence for vitamin F cosmetic promotions in the *Manufacturing Perfumer*, London, for May, states

"I have never denied—it would be absurd to do so—that fat-soluble substances may be absorbed through the skin. Rickets (vitamin D deficiency) and nightblindness (vitamin A deficiency) could doubtless be cured by external application of cod-liver oil, if we may judge by analogy from work on experimental animals. Such a method of treating a deficiency disease will hardly commend itself to those who require simplicity of administration, speed of recovery or accuracy of dosage." (Italics ours)

Concerning the relationship of absorption through animal skins and the use of vitamins in soaps, Thomas Durfee, director, Applied Research Laboratories, Inc., writing in the *Drug Trade News* for May 24, has said

"In a general consideration of the entire question of the value of the vitamins in cosmetics and toilet preparations one fact must be kept in mind. The results on which the above conclusions have been based have only covered materials that are allowed to remain on the site of application. Most of the materials used were applied by rubbing them into the skin. In view of the fact that soaps only remain in contact with the skin under practical conditions for a minute or two at most, it is questionable whether much absorption can take place during the actual washing operations. Some work has appeared in the literature to indicate that irrespective of the amount of rinsing a thin film of oil from the soap does remain on the skin. However, this film would be so slight as to permit the utilization of only a small percentage of the vitamin."

In view of these opinions it is not surprising that the Federal Trade Commission has recently published a complaint issued against a manufacturer who has made the following extraordinary claims:

"VITAMIN 'D' in Skin Soap A Wonderful Discovery of Science to Increase Your Natural Beauty!"

"Science has definitely proven that Vitamin D in Skin Soap will accomplish the following skin refinements:

- 1 Smooths out premature wrinkles
- 2 Reduces large pores
- 3 Eliminates blackheads, pimples
- 4 Corrects subnormal skin conditions, such as acne, etc.
- 5 Restores youthful color and elasticity, normalizes the action of the skin glands, refines texture"

According to the *Drug Trade News* for June 21 the complaint reads in part

"In truth and in fact said statements and representations were and are false and misleading in that it is impossible for the skin to absorb an appreciable amount of vitamin by simply washing with soap or taking a lather bath. Further Vitamin D has no effect whatsoever upon the skin or skin

⁷ Pentobarbital Sodium, N. N. R. 1937, p. 110.

⁸ Intravenous Medication (Report of the Council). *J. Am. Dent. A.* 18: 1787 (Sept.) 1931.

condition and the use of said soap will, therefore, not cure acne or any other skin disease and will not remove blackheads, pimples or other impurities. The said soap will not restore and maintain the loveliness of youth, nor will the use thereof eradicate wrinkles that are caused by fatigue.

"In truth and in fact science has not definitely proven that Vitamin D in Skin Soap will accomplish the results claimed for it, namely, to smooth out premature wrinkles, reduce large pores, eliminate blackheads and pimples, correct subnormal skin conditions and restore youthful color and elasticity."

The advertiser who proclaimed the Dawn of A Great Beauty Discovery may soon be worrying about the twilight of the day when the sky was the limit for claims about "sunshine soaps."

SERUM LIPIDS IN ECZEMA

The last decade has witnessed an extraordinary intensification of investigation designed to elucidate the biochemistry and physiology of the lipids. The number of publications dealing with these topics has doubled in the past ten years. The data from experimental work on lipids made it evident that this group of substances is significant in maintaining physiologic well being. The results are finding practical application, as shown by the use made of knowledge of the physiologic rôle of fat soluble vitamins, by the determination of the level of blood cholesterol as an aid in following the clinical course of diabetes mellitus, and by clinical application of experimental knowledge of factors influencing the concentration of abnormal quantities of lipid in the liver.

Certain essential fatty acids which apparently cannot be synthesized by the organism must be supplied in the diet in order to maintain the normal body processes. The Burrs¹ observed that young rats restricted to entirely fat-free diets do not thrive and develop a scaliness of the skin and tail, concomitant with other abnormal manifestations. They demonstrated that the changes occurring in the absence of dietary fat could be prevented or the intensity alleviated after its occurrence by the addition of either linoleic acid or linolenic acid to the diet. These two unsaturated fatty acids appear to be specific in their ability to alleviate the deficiency skin conditions occurring in rats ingesting the fat-free diet and have, therefore, been designated as essential fatty acids.

The experimental demonstration that skin changes develop in rats suffering from an unsaturated fatty acid deficiency has led to study of the possibility that certain dermatologic disorders, such as infantile eczema, might be in part related to this type of dietary deficiency. These studies have been conducted in the department of pediatrics of the University of Minnesota Medical School. In a preliminary report, Hansen² presents evidence indicating that the degree of unsaturation of

the serum lipids was less in a small group of infants with eczema than in a group of normal infants of similar ages. Furthermore, a few preliminary observations on eczematous babies given liberal supplements of unsaturated fatty acids in the diets, in addition to the routine treatment, were sufficiently encouraging to suggest the desirability of extensive study of the blood lipids in this disease.³

Although detailed cholesterol, total fatty acid content and iodine absorption values of the serum are reported for seventy normal subjects and for an equal number of patients suffering from a variety of clinical disorders, particular interest is attached to the values obtained in twenty-three infants and eight older children with eczema. Careful consideration of previous diet and study of case histories served to eliminate variables of the type of dietary habits and infections. The majority of eczematous patients showed a definite and significant lowering of the iodine number of the fatty acids of the serum when compared with normal subjects of similar ages. Furthermore, the administration to eczematous patients of large doses of oils with high iodine numbers led to a significant rise in the iodine number of the serum lipids of these patients. Moreover, concomitant with this change in blood lipid chemistry a definite improvement in the clinical condition was observed. The results obtained by Hansen are striking and suggestive of a fundamental relationship between the pathogenesis of eczema and a disturbance in lipid metabolism. Future observations in a large number of similar cases may clearly establish the value of diet in the treatment of eczema.

Current Comment

STIMULATION OF CORNEAL IMMUNITY BY IRRADIATION

The view that antibodies are locally synthesized in corneal tissues and that the resulting acquired local immunity can be multiplied twelve times by Grenz radiation is held by Thompson, Pfeiffer and Gallardo¹ of the Presbyterian Hospital, New York. The effect of irradiation on antibody production has been a controversial question for two decades. It was shown by Hektoen,² for example, that exposure to roentgen rays decreases hemolysin production in rats. Similar observations were reported by Murphy and Sturm³ in their x-ray study of precipitin and agglutinin production in rabbits. A number of recent European investigators,⁴ however, have reported stimulation of agglutinin and hemolysin production in laboratory animals as resulting from exposure to ultraviolet rays. In order to study the

effects of the intermediary grenz rays, Thompson and his co-workers injected purified egg albumin intracorneally into rabbits and determined the local precipitin titer of juices expressed from corneal tissues by the hydraulic press. Precipitins could be detected in the corneal juices earlier and in greater concentration than in the serum, spleen or bone marrow of the same animals. Rabbit eyes exposed for one minute to grenz rays on alternate days often yielded corneal juices containing from eight to twelve times the precipitin titer of juices obtained from the control antigen-injected, nonirradiated cornea. No demonstrable precipitin was present in the pooled serums of the same irradiated animals. These investigators did not interpret their results as evidence of corneal mobilization of humoral antibody under grenz ray therapy but as proof of grenz ray stimulation of local corneal synthesis of specific precipitins. Whether or not the intracellular precipitins freed by hydraulic pressure are qualitatively identical with humoral precipitins has not yet been determined.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal—Dr Carl T Martin Abbeville has been appointed health officer of Henry County succeeding Dr Wallace L Chambers resigned.—Dr George E Newton Scottsboro health officer of Jackson County has been appointed to a similar position in Lauderdale County succeeding the late Dr Wilder D Hubbard Florence.—Dr Cyril A Walwyn assistant director of the health service of Howard University Washington D C has been appointed medical director of the John A Andrew Memorial Hospital and head of the health department at Tuskegee Institute Tuskegee. He succeeds Dr Eugene H Dibble Jr who recently was appointed manager of the Veterans Administration Facility at Tuskegee.

COLORADO

Hospital Appointments—Dr Charles O Giese Colorado Springs has been appointed medical director of the Modern Woodmen Sanatorium Woodmen and Mr George Rule formerly business manager became superintendent. The appointments followed the resignation of Dr Fred A Forney medical director and superintendent who was recently made director of the new division of tuberculosis in the state department of welfare.—Dr Donald M Alderson has been appointed superintendent of Mount Airy Sanitarium Denver.

Society News—The Delta County Medical Society was addressed in Delta June 30 by Dr Edwin E Osgood Portland Ore on "Diagnosis of Heart Disease" and "Culturing of Human Bone Marrow".—At a meeting of the Crowley County Medical Society in Ordway June 25 Dr George L Pattee, Denver discussed "Infections of the Head and Neck".—Drs William V Watson Plateau City and John W Amessee Denver addressed the Mesa County Medical Society June 22 on "Past Politics and Politicians in the Medical Society" and "The Lewis and Clark Trail".

DISTRICT OF COLUMBIA

Medical Bills in Congress—*Changes in Status* H R 6696 has passed the Senate proposing to amend the Healing Practice Act of the District of Columbia by repealing the time limitation within which persons licensed prior to the effective date of that act were required to apply for a new license S 1732 H R 4876 and H R 4982 have passed the Senate proposing respectively to provide for the issuance of licenses to practice the healing art in the District of Columbia to Dr M L Perry and Dr N E Jackson to Dr Frederick W Didier and to Dr William Justin Olds H R 5110 has

also passed the Senate providing for the issuance of a license to practice chiropractic in the District of Columbia to Russell V Pemberton H R 4536 has been reported to the Senate directing the Board of Optometry of the District of Columbia to examine Welton B Hutton for a license to practice optometry in the District. *Bill Introduced* S 2837 introduced by Senator King Utah proposes to regulate the manufacturing, dispensing, selling and possession of narcotic drugs in the District of Columbia.

FLORIDA

Protest Against Socialized Medicine—The executive committee of the Florida Medical Association at a meeting in Orlando June 24 adopted a resolution recording its opposition to and its unwillingness to cooperate in any plan that involves federal supervision and control of medical practice in the United States. The committee affirmed the willingness of the association to cooperate at all times with the proper authorities in order to secure adequate medical care for all indigent persons but pointed out that at the same time it is convinced that such care is distinctly a community responsibility and is properly a function of local government and the local medical profession. Federal supervision of the medical care of the indigent without local control by the component medical units of the state medical societies will destroy the principles that maintain for the public the highest quality of medical service and the possibility of improvement in the service the committee declared.

ILLINOIS

Premarriage Tests Tax Laboratories—The new state law requiring premarriage tests for venereal disease has taxed the facilities of state laboratories to the point that the Kahn test has been adopted for blood tests instead of the Wassermann test. The Chicago *Tribune* reports Dr Frank J Jirka state director of public health issued suggestions to physicians July 17 to expedite the work. It is necessary he pointed out that the full name of each person who wishes a report for a marriage license must be inserted on the form and that separate reports be made for each of the two people who propose to marry with the two laboratory reports attached to each. He also asked that physicians do not enclose smear specimens for microscopic examination with blood specimens as the slides are frequently broken. Since the law requires only a microscopic test for gonorrhea physicians are asked not to request a complement fixation test. Finally Dr Jirka asked those who send specimens to mark them For Marriage License in order that the volume and value of work done in compliance with the law may be appraised.

Chicago

Annual Golf Tournament—The Chicago Medical Society held its annual golf tournament at the Medinah Country Club July 28. Three hundred persons including guests played in the tournament. Dr Edward A Brucker with a score of 79 won the Vanderslice Memorial Cup the principal award for the officers of the society. Dr Hubbard P Saunders with an 81 placed second winning the Councilor's Trophy. Dr Frank S Needham Oak Park Ill was third with a score of 82. Dr Charles H Phifer won the Past President's Cup with a 95 low gross and Dr James H Hutton the low net with a 77. The hospital team tournament was won by Ravenswood Hospital and Cook County placed second.

INDIANA

University News—The research committee of Indiana University School of Medicine Indianapolis has released \$3 000 to the cancer clinic at the school for the purchase of additional radium.

Election of State Board—Dr Edmund M Van Buskirk Fort Wayne was elected president of the Indiana State Board of Health at a meeting in Indianapolis July 15. Dr William Wise Indianapolis was appointed to the board as a new member and Drs Ernest Rupel Indianapolis and John C Glackman Rockport were reelected.

Personal—Dr Guy G Campbell East Gary has been appointed head of the medical staff of the Firestone Plantation Liberia Africa.—Dr Antonio Giorgi, Gary, has been appointed a member of the board of the Central State Hospital, Indianapolis.—James D Sturgis, Indianapolis, deputy attorney general has been appointed legal counsel for the Indiana State Board of Health; he will give all his time to the legal phases of the board's work.—Dr Bert E Moore Danville Ill has been appointed superintendent of the Knox County Tuberculosis Hospital now under construction at Vincennes.

KANSAS

Society News—Dr Lyle S. Powell Lawrence presented an illustrated lecture before the Southeastern Kansas Medical Society in Neodesha June 17, on "A Medical Man in India and China."—Members of the Saline County Medical Society gathered for golf and trap shooting followed by a picnic at the cabin of Dr William E. Mowery near Salina July 15.

Graduate Courses—The third of a series of graduate courses, financed with social security funds and sponsored by the state board of health in conjunction with the committee on maternal and child welfare of the state medical society, was opened in the northeast area August 9 to continue to September 3. Pediatrics and obstetrics will be discussed in five towns once a week for four consecutive weeks. Topeka, Manhattan, Marysville, Hiawatha and Atchison. Instructors will be Drs Frank C. Neff and Leroy A. Calkins, Kansas City, Mo., professor of pediatrics and professor of obstetrics and gynecology respectively, University of Kansas School of Medicine, Kansas City, Kan.

LOUISIANA

Work Begins on Charity Hospital—Construction on the new Charity Hospital, New Orleans began July 12. The project will cost \$12,500,000. The main building of the hospital was condemned and will be replaced with a twenty-story modern unit ultimately providing for 2,470 patients. One of the new features will be a disinfecting station through which every patient admitted must pass and where he will have a bath and if necessary a haircut and shave while his clothes are being sterilized. From the sterilizer the clothes will be sent to the rehabilitation department where they will be mended so that on discharge the patient will receive a sterile packet containing his clothes in better condition than they were when he entered the hospital.

MASSACHUSETTS

New Hospital Buildings Dedicated—A new hospital building and an infirmary at the Taunton State Hospital, Taunton, were dedicated June 23. The two buildings, representing an investment of about \$1,000,000, are part of a program which includes six buildings, one for the treatment of acute recoverable mental cases, a hospital, an infirmary for men, an infirmary for women, a building for the treatment of acute exacerbations in the continued treatment types and a kitchen and dining room unit. This group when completed is designed to accommodate all patients needing active treatment for either mental or physical illness in a hospital of 2,000 patients. The hospital just dedicated contains a nurses' training school, pharmacy laboratories, operating suite, x-ray department, physical therapy department, dental suite, quarters for sick employees and a ward for each sex accommodating about fifty patients. It includes also facilities for the isolation of contagious diseases and the wards are equipped in such a manner as to enable both medical and surgical cases to receive adequate treatment. The infirmary has three floors for the care of the infirm and one for those suffering with tuberculosis. It has a capacity of 200 patients. The speakers at the dedicatory ceremony included Mr. Andrew H. Peterson, state director, Massachusetts Public Works Administration; Brig. Gen. Charles H. Cole, representing the governor, and Dr. Albert Warren Stearns, Boston, associate commissioner, state department of mental diseases.

MICHIGAN

Personal—Dr. Robert Howell, assistant superintendent of Eloise Hospital, Eloise, was presented with a chair and floor lamp, July 17, by the nurses and ward supervisors at the hospital, in recognition of his thirty years service with the institution.—Physicians from Otsego, Montmorency, Oscoda, Roscommon, Crawford and Ogemaw counties were guests at the home of Charles G. Saunders, DDS, Gaylord, for their annual meeting, July 8, at which a gift was presented to Dr. Levi A. Harris, Gaylord, to mark his completion of fifty-one years in the practice of medicine.

University News—During the centennial celebration of the University of Michigan Ann Arbor, June 14-19, speakers included Drs. Alice Hamilton, professor emerita of industrial medicine, Harvard University Medical School, Boston, who presided at a general discussion on "Higher Education and Scientific Progress"; James R. Arneil, Denver, "The Future Responsibilities of the Professional Man"; and Bertha Van Hoosen, Chicago, "The Contributions of the Machine Age to Medicine."—Dr. Isadore Lampe, instructor in roentgenology, University of Michigan Medical School, has been appointed

hospital statistician, succeeding Dr. H. Marvin Pollard, who will devote his entire time to his positions as instructor in internal medicine and secretary of the medical school.

Progress of Tuberculosis Campaign—From February 1, when the campaign against tuberculosis in Detroit was begun, up to July 2, 41,434 tuberculin tests had been made according to the *Detroit News*. Of these 10,010 gave positive results. Of 10,010 persons in whom the test was positive, 7,403 had x-ray examinations and it was found that 313 had active tuberculosis. In 45 per cent of these the infection was minimal. The *News* discusses the financial aspect of the early detection of tuberculosis as follows:

Records of Herman Kiefer Hospital show that the average cost of treating an advanced case of tuberculosis is \$1,620 a year. The average cost of treating a minimal or early case is \$810 a year. The difference is \$810, a 50 per cent saving on each case. Treating 140 cases early—instead of allowing these cases to become advanced and finally come to treatment at city expense—therefore has effected a saving of \$113,400 in only five months. This saving on the assumption that the 140 may be put back into economic circulation at the end of a year would amount to \$1,585,920 on an annual basis of the campaign. These figures, however, must be taken with certain reservations since a large number of patients with advanced tuberculosis are now saved and ultimately get back to normal earning ability.

MISSISSIPPI

Personal—Dr. Joseph B. Thigpen, Bay Springs, has been appointed health officer of Jasper County, effective July 1. Dr. Edward C. O'Cam, Winona, of Montgomery County, succeeding Dr. James P. Synnott; and Dr. Archie S. Calhoun, Mount Olive, of Covington County, succeeding Dr. George T. Cranford Seminary.—Dr. Thomas J. Brown, Grenada, was guest of honor at a dinner in Coffeeville given in celebration of his seventy-fifth birthday. He formerly lived in Coffeeville.

Poliomyelitis Outbreak—About 225 cases of poliomyelitis have been reported to the Mississippi State Board of Health from January 1 through August 4. The board reports. The outbreak is principally in the central and southern counties, the largest number of cases, twenty-seven, having appeared in Leake County. A temporary corrective treatment clinic has been set up in Jackson by the crippled children's division of the state department of education and the state board of health to give immediate corrective aid to recent victims of the disease. These patients are not admitted for long stays and are admitted only after a period of from seven to ten days after the onset of paralysis. The corrective treatments are being given by trained orthopedic surgeons and a follow-up home nursing service is furnished to instruct mothers in the management of the patients at home.

MONTANA

University News—Donald M. Hetler, Ph.D., assistant professor of bacteriology and immunology and of public health, Washington University School of Medicine, St. Louis, has been appointed head of a new department of bacteriology and public health at the University of Montana, Missoula. New courses in bacteriology of foods and water and a course in public health and sanitation will be added to the curriculum of the department. Bacteriology was formerly taught in connection with the department of zoology.—Dr. Charles G. Sale, Birmingham, Ala., has been appointed assistant to Dr. Meredith B. Hesdorffer, head of the university health service.

NEW JERSEY

Personal—Dr. Joseph B. Harrison, Westfield, attended his sixty-first consecutive annual meeting of the state medical society when it convened in Atlantic City in April.

Hospital News—The cornerstone for an addition to the Hospital of St. Barnabas and for Women and Children, Newark, was laid in June. The new building will bring together at one site the Hospital of St. Barnabas and the Hospital for Women and Children, which were merged several years ago but have remained in their separate buildings. The building of the latter will be abandoned. The new addition will provide seventy-nine more beds and will have a surgical floor with a separate obstetric department, x-ray department and a fully equipped laboratory.

Court Upholds Max Plager's Blood Pressure Business—The supreme court of New Jersey recently sustained a decision of the Atlantic County court acquitting one Max Plager, who takes the blood pressure of his customers in a concession on the Boardwalk at Atlantic City, of the charge of practicing medicine illegally. The justice said in an opinion handed down July 22 that blood pressure was not a disease and thus far the law did not restrict its determination to physicians. Newspapers stated that Plager offered evidence to show that he did not give medical advice. The state board of medical examiners prosecuted the case.

NEW YORK

Lake Keuka Meeting—The annual meeting of the Lake Keuka Medical and Surgical Association was held in Penn Yan June 24 with the following speakers on the program

Dr Henry J John Cleveland Protamine Zinc Insulin
Dr Geza de Takats Chicago Treatment of Convulsive Seizures Not Due to Epilepsy
Dr Claude F Dixon Rochester Minn Cancer
Dr Stafford L Warren Rochester N Y Treatment of Venereal Disease by Fever Therapy

Dr Howard W Haggard New Haven Conn, gave an address at an evening banquet on 'Medicine and the Public'

Emergency Relief Merged with State Agency—The Temporary Emergency Relief Administration created in 1931 by the state legislature to provide for the unprecedented relief needs then existing was merged July 1 with the state department of social welfare. Many members of the staff of TERA have been added to the staff of the state department but many positions not essential have been discontinued. Local units are allowed to continue the emergency relief machinery for a year if they so desire. It was said however that up to June 20 only four cities and three counties had taken advantage of this option.

Society News—Dr Richard Kovacs New York addressed a joint meeting of the Broome County Medical Society, the Binghamton Academy of Medicine, the Binghamton Psychiatric Society and the Endicott Johnson Medical Society June 1 on the role of physical therapy in the treatment of nervous and mental disease. At the quarterly meeting of the Ontario County Medical Society at Clifton Springs July 13 Dr George B Adams director of the Cayuga County Laboratory Auburn spoke on "Some Ways that Laboratory Medicine Can Be Used Advantageously in Clinical Medicine."—Dr William J Engel Cleveland, addressed the Medical Society of the County of Niagara Niagara Falls June 8 on 'Urologic Problems in Childhood'

New York City

Personal—Dr Joseph Wortis addressed a meeting sponsored by the Swiss Psychiatric Society in Bern in May on "Early Experiences with Sakel's Hypoglycemic Insulin Treatment of the Psychoses in America."—Dr James Alexander Miller received the honorary doctorate of public health at the recent annual commencement of New York University.—Dr Royal Whitman has been elected an honorary fellow of the Royal Society of Medicine of London.

Residency in Hospital Administration Available—The Hospital for Joint Diseases announces that there will be available Jan 1 1938 a residency in hospital administration for a three year term. Requirements are graduation from a class A medical school two years' general internship in a hospital of at least 200 beds reliable testimony as to personal qualities and a desire to make hospital administration a life work. Full maintenance will be provided with a stipend of \$600 the first year \$900 the second and \$1200 the third. Applications should be addressed to Dr Jacob J Golub director of the hospital Madison Avenue and 123d to 124th streets New York.

Memorial Hospital Building—Ground was broken for a new building for Memorial Hospital for the Treatment of Cancer and Allied Diseases in the block bounded by Sixty-Seventh and Sixty-Eighth streets York and First avenues June 8 in the presence of the board of managers and the medical staff. The new hospital which will adjoin the Rockefeller Institute for Medical Research New York Hospital and Cornell University Medical College will contain 168 beds and will provide facilities for diagnosis and treatment research laboratories and outpatient service. Dr James Ewing is director of the hospital and president of the medical board. The site was donated by John D Rockefeller Jr and the General Education Board has provided \$3 000 000 for the building and equipment.

Speech Clinic to Be Enlarged—Mr Lucius N Littauer, New York manufacturer has given to the National Hospital for Speech Disorders founded in 1916 a gift of between \$200,000 and \$225 000 to expand the institution to include research and teaching as well as treatment. It will be removed from its present location at 126 East Thirtieth Street to 61-63 Irving Place which will be remodeled and renamed the Lucius N Littauer Institute for Speech Disorders. Dr James Sonnet Greene founder and medical director of the hospital will be medical director of the new institution. Mr Littauer will be president and Dr Bernard Sachs vice president. About 156 000 treatments more than three fourths of them free, were given in the hospital last year according to an account in the New York Times.

OHIO

Personal—Dr Homer S West St Clairsville has been appointed health officer of Belmont County succeeding Dr Archie J Martin who resigned to enter private practice in Adena.—Dr William E Thompson Bethel celebrated his one hundred and second birthday July 6.

Hospital Bequest—St Luke's Hospital Cleveland is to receive 70 per cent of the estate of Mr Francis Fleury Prentiss, estimated at \$3 000 000. Mr Prentiss gave authority to the board of trustees to use the money as it may determine, but definite plans have not been formulated. Settlement will probably not be made for more than a year it was said.

Dr Moritz Appointed Professor at Harvard—Dr Alan Richards Moritz associate professor of pathology Western Reserve University School of Medicine Cleveland has been appointed professor of legal medicine at Harvard University Medical School Boston. Dr Moritz will spend two years in Europe studying before entering on his work at Harvard. He is 37 years old and a graduate of the University of Nebraska College of Medicine Omaha class of 1923.

PENNSYLVANIA

Society News—Dr Jesse L Lenker Harrisburg addressed the Medical Society of Cumberland County at Carlisle recently on 'Acute Rheumatic Fever'.—The Cambria County Medical Society held its annual outing at the Summit Country Club Cresson August 12.

Hospital News—A unit for thoracic surgery was recently begun at the State Tuberculosis Sanatorium, Hamburg with an appropriation of \$150 000 granted by the legislature of 1936. The new unit will accommodate thirty-eight patients and will be equipped with two operating rooms an x-ray department and offices for physicians.

Philadelphia

University News—The estate of Miss Frances T Kinsey providing a fund of about \$200 000 to the University of Pennsylvania School of Medicine for study of digestive disorders was adjudicated in the Orphans Court recently. The fund to be known as the Kinsey-Thomas Foundation for the Study and Treatment of Diseases of the Digestive System will be under the direction of Dr Thomas Grier Miller.

Hospital News—The Mary Ann McCarthy Clinic, devoted to treatment of diabetes was opened June 24 at St Agnes' Hospital. The clinic was presented to the hospital by John A McCarthy banker and civic leader, in honor of his mother. Dr Anthony Sindoni Jr is in charge.—The annual graduating exercises for interns completing their service at the Philadelphia General Hospital was held June 24. Dr David Riesman president of the medical board presented diplomas and an award of \$100 to Dr William James Hanes for an original paper on 'Certain Endocrinological Observations in Exfoliative Dermatitis'.

Dr Pancoast Honored—The July issue of the *American Journal of Roentgenology and Radium Therapy* was dedicated to Dr Henry K Pancoast in honor of his twenty fifth year as professor of roentgenology at the University of Pennsylvania. In 1912 the university created the chair of roentgenology in the medical school and appointed Dr Pancoast professor. Dr Pancoast has served as president and secretary of the American Roentgen Ray Society and the American Radium Society as president of the American College of Radiology and as chairman of the Section on Radiology of the American Medical Association. He was president of the first American Congress of Radiology held in Chicago in 1933.

TEXAS

State Board Changes—Dr Oliver B Kriel Wichita Falls, was elected president of the Texas State Board of Medical Examiners at a recent meeting. Dr Wiley C Morrow Greenville was made vice president and Dr Thomas J Crowe Dallas reelected secretary. Dr John T Lawson Bowie, was recently appointed to the board to succeed Dr Joseph Allen Kyle Houston.

Personal—Dr Edythe P Hershey director of the child health and maternity divisions of the state health department has been appointed to the staff of the division of maternal and child health in the Children's Bureau of the U S Department of Labor to make a special study of facilities for maternal care. Dr Hershey was formerly director of school health in the Dallas school system.

VIRGINIA

Society News—Among the speakers at a quarterly meeting of the Southside Virginia Medical Association in Petersburg June 15 were Drs Guy W Horsley Richmond on "Surgery in the Aged" Porter P Vinson Richmond, "Significance of Dysphagia" and Charles S Dodd Petersburg, "Glaucoma and Optic Atrophy."

Changes in Health Officers—Dr William H Walcott, Chatham has resigned as health officer of Pittsylvania County to accept a position on the staff of the U S Public Health Service in Washington D C His successor is Dr Benjamin R Allen, Luray—Dr Walter R Parker, Woodland, N C, has been appointed health officer of Northampton County

WASHINGTON

State Medical Election—Dr Arthur Betts Spokane was chosen president-elect of the Washington State Medical Association at the annual meeting in Seattle July 21 Dr Delmar F Bice, Yakima vice president and Dr Vernon W Spickard Seattle was reelected secretary Dr J Reid Morrison Bellingham was installed as president. The 1938 convention will be held in Bellingham

WYOMING

State Medical Election—Dr Victor R Dacken Cody was installed as president of the Wyoming State Medical Society at the annual meeting of the house of delegates during the Rocky Mountain Medical Conference in Denver July 19-20 Dr John D Shingle Cheyenne was chosen president-elect Dr Emory W DeKay Laramie vice president and Dr Marshall C Keith Casper secretary Dr Keith was appointed editor of the Wyoming section of *Colorado Medicine* The 1938 session will be held in Laramie

ALASKA

Meningitis Epidemic—Newspapers reported August 1 that a meningitis epidemic has broken out in scattered Indian villages on the Yukon River It was said that Dr Maurice E Corthell of the United States Hospital for Natives, Mountain Village was visiting the settlements in a hospital boat Six deaths were reported A plane ready to take serum to the distant villages was said to have been kept on the ground by adverse weather

GENERAL

Officers of National Research Council—Dr Ludwig Hektoen Chicago has been reappointed chairman of the National Research Council for the year beginning July 1 Dr Esmond R Long Philadelphia is chairman of the division of the medical sciences and Dr Howard T Karsner Cleveland vice chairman

American College of Chest Physicians—The Federation of American Sanatoria at its annual meeting in Atlantic City June 7 voted to change its name to the American College of Chest Physicians Dr Champneys H Holmes Atlanta Ga was chosen president-elect of the organization and Dr Edward W Hayes Monrovia Calif is president Dr Frank W J Burge Philadelphia has been elected chairman of the editorial board and editor of *Diseases of the Chest* official organ of the society to succeed Dr Charles M Hendricks El Paso

Society News—The Academy of Physical Medicine will hold its fifteenth annual meeting at the Hotel Walton Philadelphia October 19-21—The National Association for Nursery Education will hold its annual meeting in Nashville Tenn October 20-23 Among the speakers will be Dr Martha M Eliot of the Children's Bureau Washington D C—The twenty-seventh annual session of the American College of Surgeons will be held in Chicago at the Stevens Hotel October 25-29—The American Association of Anatomists has voted to hold its next annual meeting at the University of Pittsburgh School of Medicine April 14-16 1938

Fraudulent Subscription Agents—The circulation office of the weekly magazine *Life* reports that many physicians in the New York area have written concerning the activities of two men who are soliciting subscriptions to the magazine and appear to be concentrating on the medical profession They use the names George Cowan and Larry Hardes and are said to be misquoting prices and pocketing the money turned over to them by subscribers In most cases they offer a special price of \$4 for the magazine with a ten volume encyclopedia as a premium Cowan gives his address as 350 East Twenty-Second Street Chicago the former address of the circulation department of *Life* Neither of these men has been authorized

to represent *Life* the office reports Their activities have been reported to the National Publishers' Association 232 Madison Avenue, New York, which is endeavoring to apprehend and prosecute the men

Medical Bills in Congress—*Changes in Status* The President signed, August 2 the Marihuana (Cannabis) Tax Act of 1937 and August 5 the National Cancer Institute Act S 2463 has passed the House with amendments proposing (1) that there shall be four assistants to the Surgeon General of the Army with the rank of brigadier general one of whom shall be an officer in the Dental Corps (2) that there shall be an increase of 100 officers in the Medical Corps of the Army and an increase of fifty officers in the Dental Corps and (3) that service as Contract Dental Surgeons and Acting Dental Surgeons shall be credited to the officers of the Dental Corps for the purpose of retirement H R 4716 has passed the Senate proposing to construct a Marine Hospital in Florida H R 6283 has passed the Senate proposing to increase the punishment of second third and subsequent offenders against the narcotic laws H R 8099 has been reported to the House proposing to amend certain administrative provisions of the Tariff Act of 1930 The bill among other things provides that professional equipment and tools of trade imported for personal use by nonresidents sojourning temporarily in the United States may be admitted without the payment of duty *Bills Introduced* S 2880 introduced by Senator Sheppard, Texas proposes to amend the Social Security Act by providing grants to the states for assistance to needy incapacitated adults defined to mean 'needy individuals who are eighteen years or more of age and are permanently incapable of self support by reason of a physical disability or defect and not mental' S 2917 introduced by Senator Guffey Pennsylvania and H R 8148 introduced by Representative Walter Pennsylvania propose to provide that the Robinson-Patman Antitrust Act shall not apply to purchases of their supplies for their own use by schools colleges universities public libraries churches hospitals and charitable institutions not operated for profit and supported in whole or in part by public subscriptions H R 8131 introduced by Representative Terry, Arkansas proposes to appropriate the sum of \$5,000,000 and to authorize a similar appropriation each fiscal year for four consecutive years to enable the states to make adequate provision of hospital beds for tuberculous patients H R 8189 introduced by Representative Maverick Texas proposes to create an unemployment commission to investigate the problem of unemployment in the United States with authority to study among other things the nature and extent of ill health

Changes in Status of Licensure—The State Board of Medical Examiners of Florida reports the following action taken June 14

Dr Roy Webb Palm Beach license revoked for narcotic violation
Dr Feliciano Gonzalez Jacksonville license revoked for narcotic violation

The Indiana State Board of Medical Registration and Examination reports the following action taken at its meeting July 13

Dr Sidney J Eichel Evansville license revoked for violation of the Harrison Narcotic Act
Dr Peter C Berns Jr Linton license revoked for violation of the Harrison Narcotic Act

The Massachusetts Board of Registration in Medicine announces the following action taken at its meeting July 15

Dr Hans W Bencker Boston license restored
Dr William H H Briggs Haverhill license restored

The Minnesota State Board of Medical Examiners reports the following action taken at a meeting June 29

Dr David Hamilton Nushbaum Jackson license revoked because of his conviction of violating the Harrison Narcotic Act
Dr Walter Bertram Clement Shakopee license revoked he was found guilty of immoral dishonorable and unprofessional conduct following the death of a 24 year old girl

The New York State Board of Medical Examiners reports the following action

Dr Elmer L Hunman whose last known address was 13 West On Hundredth Street New York license revoked recently for conviction of a felony

The State Board of Medical Examiners of Oklahoma recently reported the following action

Dr Young Anderson Howell whose last known address was Mountain View Okla license restored June 10 it was suspended June 11 1936

The Pennsylvania State Board of Medical Education and Licensure reported the following actions taken at a meeting June 29-30

Dr John Lang Winslow, Pittsburgh license indefinitely suspended on evidence of unethical practice he was shown to be protecting an illegal practitioner Harry Fabian who was prosecuted by the board and fined \$500 with a six months suspended jail sentence

Dr David A Rupert Donora license restored it was revoked Aug 27 1936

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 17, 1937

Toxic Effects of Sulfanilamide and Related Compounds

Sulfanilamide was first used in this country for the treatment of puerperal fever due to hemolytic streptococci. Its use was then extended to infections due to other organisms—meningococci, pneumococci, gonococci and the enteric group. More recently it has been used in erysipelas and rheumatic fever. As a rule, toxic symptoms have been slight, but in a few cases they have been serious and even fatal. Paton and Eaton in the *Lancet*, May 15, reported from Glasgow instances of sulfhemoglobinemia and methemoglobinemia following the administration of sulfanilamide. One case was especially severe. A woman, aged 28, was admitted to hospital for puerperal pyrexia with alarming cyanosis. The blood gave the spectrum of sulfhemoglobin. She had been taking magnesium sulfate as well as sulfanilamide (9.6 Gm of prontosil album in four days). Cyanosis was conspicuous in the face lips and finger nails and she was apparently moribund, but she recovered under treatment, which included administration of oxygen and blood transfusion. It was suggested by Colebrooke and Kenny last year that sulfanilamide poisoning might be associated with the administration of sulfates. Paton and Eaton investigated the question and have found that administration of magnesium sulfate with sulfanilamide produces sulfhemoglobinemia in most persons.

A more serious effect of sulfanilamide is agranulocytosis. C. J. Young in the *British Medical Journal*, July 17, reported a case of acute rheumatism which did not respond to salicylates. A man, aged 53, was given 3 Gm daily of prontosil album for eighteen days. At the end of this period his clinical condition had deteriorated, the temperature being higher than before, and the treatment was stopped. Four days afterward complete agranulocytosis was found and blood culture, previously negative, showed hemolytic *Staphylococcus aureus* and *Streptococcus viridans*. Death occurred on the following day. The necropsy showed membranous pharyngitis. There were no granular cells in the red marrow. Death was considered to be due to agranulocytic angina with septicemia. A feature of the case was failure of serial leukocyte counts to give warning of the impending disaster. Another fatal case of agranulocytosis was recorded in the *Lancet*, June 26, but from Amsterdam, by Borst. Prontosil flavum was given. After this case he used sulfanilamide and also found toxic effects, but they were mild.

On the other hand, the most recent report as to the value of 'prontosil' in puerperal fever is favorable. At the annual meeting of the board of Queen Charlotte's Maternity Hospital the chairman, Sir Samuel Scott, said that the use of prontosil was begun in the isolation block last February. Its use was confined to infection with the hemolytic streptococcus, which was responsible for the great majority of the severe and fatal cases. Instead of losing one out of every five of the mothers with this dangerous form of puerperal fever as they had since 1930, they lost only one in twenty. There were five deaths and of these two cases were quite hopeless when the patients were admitted.

Ovarian Extroversion for Secondary Amenorrhea

Before the North of England Obstetrical and Gynaecological Society Dr K. V. Bailey gave his results from an operation (which he first described to the society eighteen months ago) for the restoration of the function of cirrhotic and cystic ovaries, by facilitating the approach of the follicles to the surface. He excises a wedge from the ovary sagittally, having its base at the periphery and its apex in the region of the hilus. He then passes sutures through the ovary in such a way as to turn the cut edges of the ovary partially inside out. Of seventeen

patients thus operated on, thirteen began to menstruate immediately afterward and there were four failures. With regard to the treatment of such cases by endocrine extracts, unscientific optimism had replaced unreasonable skepticism, but he believed that this treatment should be tried first in all cases of secondary amenorrhea. If it failed, extroversion of the ovaries should be tried, but the patient should be told that success could not be promised. The regularity with which menstruation followed the operation in the majority of his cases strongly suggested ovulation from ovaries which showed no recent or remote evidence of it. Proof of such ovulation was, however, not obtained by him until one patient, who had amenorrhea for two years and three months and showed no trace of a corpus luteum at operation, became pregnant. In this case regular menstruation began five weeks after operation and continued regularly for two years until the advent of pregnancy. In the successful cases some stimulus to menstruation was evidently established by the operation. In Bailey's opinion this was ovulation. He recognized that laparotomy should not be performed before a thorough trial had been given to general and endocrine treatment, but when this failed he held that his operation was justifiable with the object of restoring normal menstruation and of improving the prospects of pregnancy, provided all concerned realized that success could be expected in only 75 per cent of cases.

England's Coroners to Be Lawyers

According to the coroners' amendment act of 1926 a coroner must be either a lawyer or a physician. But there recently has been a tendency to appoint only lawyers, which has aroused protest in the medical profession. The argument is that the medical knowledge required at an inquest is provided by the medical witness. The London County Council has decided that in future only lawyers will be eligible for appointment as coroners. Heretofore both legal and medical qualifications have been required. The committee of the council concerned recommends the change subject to due weight being given to experience as deputy coroner and knowledge of forensic medicine. At the meeting it was stated that all the present London coroners were physicians who had qualified as barristers, but this was only 'a paper qualification', they had no experience in legal administration. In the debate medical members of the committee opposed the change. Dr S. M. Copeman said that it was regrettable that the committee was departing from a practice now twenty years old. It was likely that the powers of coroner would be curtailed in the future and that they would have little more to do than determine the cause of death. A physician was better qualified than a lawyer to do that.

New Safeguards to the Adoption of Children

Grave scandals in connection with the adoption of children (what is called "baby farming") have led to proposals for its regulation by a departmental committee of the House of Commons. The societies and other agencies for adoption are performing a useful function but their methods are open to improvement. The committee recommends that adoption agencies should be licensed and that licenses be granted subject to conditions, such as that the agency is a bona fide charitable society and that those employed by it are fit persons for the work. It thinks that to prevent private persons from arranging adoptions would be unreasonable, though the risks of such adoptions are great. It recommends that there should be a duty of notification to the local infant protection authority on both the agent and the person receiving the child. The age limit for privately arranged adoptions should be 16 years in view of the risk that adolescents might be adopted as a means of obtaining cheap labor or for other undesirable reasons. There should be general regulation and supervision of the work of the licensed agencies, a thorough medical examination of the child, and inquiries into the social and medical history of its parents.

Poisonous Gases in Industry Hydrogen Sulfide

The Department of Scientific and Industrial Research has issued the first of a series of leaflets describing standard methods for the detection of toxic gases in industry. The present leaflet deals with hydrogen sulfide, which is very poisonous. In concentrations of one part in 1,000 by volume of air it is nearly as poisonous as prussic acid, in concentrations of one part in 10,000 it produces irritation in the eyes and throat after one hour's exposure. It is emphasized that reliance cannot be placed on the sense of smell as a guide to safety, because persons differ greatly in their ability to detect smells, and, moreover, the sense of smell readily becomes tired and then is of little value in noting even much increased concentrations. Finally, the smell of hydrogen sulfide may be masked by other odors. The test recommended is to draw a known volume of the atmosphere under test through test paper treated with lead acetate fitted to a hand pump. The paper is stained brownish by concentrations as low as one part in 150,000.

Late Effect of Mustard Gas on the Eye

Before the section of ophthalmology of the Royal Society of Medicine, Mr. Frank Heckford reported the case of a man, aged 41, who was exposed to mustard gas during the war. Some time elapsed before he received treatment. He was many months in the hospital for "eye trouble" but eventually appeared to be cured. He did not complain of further symptoms until August 1932. At present the conjunctivae have a porcelain-like appearance. There is loss of substance of the cornea and vertical folding apparently in Descemet's membrane. With a slit lamp a crystallizing effect is seen in the substance of the cornea. Corneal sensation is unimpaired except over the destroyed areas. The fundi show nothing abnormal. Vision is 6/36 but can be improved to 6/18 in the right eye and to 6/24 in the left by correction of the refraction. No case of such late destructive effect of mustard gas on the eye appears to have been previously observed in this country.

The Carrying of Oxygen During High Flights

The Air Ministry intends to make the carrying of oxygen compulsory during flights by commercial aircraft at very high altitudes. For flights in which an altitude of 15,000 feet above sea level is reached otherwise than in an emergency, a supply of oxygen, with an apparatus for its use by passengers and crew in case of need, must be carried and placed under the control of a member of the crew. Notice of this intended amendment to the Air Navigation Directions is given so that owners may make provision for the necessary equipment before the regulation is made compulsory. It is rare at present for British airplanes to reach such high altitudes. The new rule is intended as a precaution to ensure the safety and comfort of passengers and crew when commercial flying may extend to the stratosphere.

London's Water Supply in Air Raids

As previous letters to THE JOURNAL show, all possible precautions for the protection of the civilian population in air raids are being taken. Thus the Metropolitan Water Board of London has decided to appoint an air raids precautions officer at a salary of not less than \$3,500 per annum. In consultation with the government, the board has prepared a provisional scheme for the maintenance of the water supply of the population of London during an air raid. The scheme includes the provision of a portable plant, the protection of the principal pumping stations and works, and the protection of the operating staff.

The Control of Malaria

Some 120 nonmedical men—planters, mining engineers and others—have recently attended a course on the control of malaria at the London School of Hygiene and Tropical Medicine. In a letter to the *Times*, Sir Malcolm Watson, director of Ross Institute of Tropical Hygiene, refers to the difficulty

of there being so many mosquitoes and of such various habits. The great majority do not carry malaria, and in various parts of the world it has been possible to eliminate the dangerous species. In 1904 the planters of Malaya became interested and led the way to the successful application of Ross's discovery to two towns. From Malaya, business men carried the work to India. Tea estates of 400,000 acres and a population of a million are gradually bringing malaria under control.

The Chair of Anatomy at the University of Manchester

F. Wood Jones, professor of anatomy in the University of Melbourne, has accepted the invitation to fill the chair of anatomy in the University of Manchester, to succeed Prof. J. S. B. Stopford, who has asked to be relieved in view of his administrative work as vice-chancellor of the university. F. Wood Jones has held professorships in the London School of Medicine for Women (anatomy), the University of Adelaide (anatomy) and the University of Hawaii (anthropology), in addition to his Melbourne appointment, on which he entered in 1930. Among his numerous published works are *Coral Atolls*, *Arboreal Man*, *The Mammals of Australia* and *Man's Place Among the Mammals*.

The Editorship of the Lancet

Dr. Egbert Morland has been appointed editor of the *Lancet*, in succession to Sir Squire Sprigge. He has been assistant editor since 1915. Dr. T. F. Fox and Dr. M. H. Kettle have been appointed assistant editors.

PARIS

(From Our Regular Correspondent)

July 14, 1937

The American Hospital Needs Financial Help

An appeal for financial aid which appeared in the June 16 Paris edition of the *New York Herald* pointed out that the American Hospital of Paris rendered services in 1936 to Americans who were unable to pay, to the amount of \$68,897. The budget of the hospital shows a constantly increasing deficit, which was \$22,000 last year. This is too large a sum for the American colony in Paris, which has been greatly reduced in numbers since 1933, to shoulder alone. The hospital could be kept open by refusing to treat free cases but does not wish to accept this solution of the question. Every visitor to France or resident is being asked to send a check to support this institution of 150 beds. The annual subscription asked for, from all those interested in having all the facilities of an American hospital at their disposal while in Europe, is only \$20. Checks can be sent to Mr. Bernard S. Carter, 14 Place Vendôme, Paris.

A campaign with the definite object of raising \$150,000 is also being launched. Ambassador William C. Bullitt and General John J. Pershing will head a committee for this purpose, composed of prominent Americans. Up to July 13, over \$51,000 had been subscribed.

Social Insurance During 1934 and 1935

A report submitted by the minister of labor has just been published in the *Journal officiel*. On Dec. 31, 1933, 10,000,000 individuals who were engaged in commercial pursuits and 1,150,000 who were engaged in farming and forestry were insured. The dues paid by the insured from 1930 (when the law was put into effect) to 1935 inclusive, were as follows:

1930	1 496 million francs
1931	3 562 million francs
1932	3 261 million francs
1933	3 272 million francs
1934	3 176 million francs
1935	3 086 million francs

The franc from 1930 to July 1, 1933, was equal to about 4 cents, and from the latter date to the end of 1935 to about

5 cents The decrease in dues or premiums paid during 1934-1935 was in all probability the result of widespread unemployment

As to the expenditures from 1930 to 1935 inclusive, the amounts paid out for sickness claims were as follows

1930 1931	714 million francs
1932	876 million francs
1933	935 million francs
1934	989 million francs
1935	1 076 million francs

During the earlier years, there were fewer claims for sickness insurance than during the period of decreased employment

The amounts paid out for maternity insurance were as follows

1930 1931	156 million francs
1932	178 million francs
1933	170 million francs
1934	172 million francs
1935	169 million francs

The slight changes in maternity claims, from year to year, parallel the lack of increase in the number of births in France during the same period The insured workers and their employers each pay half of the premium every three months to the local bureaus, termed in France the "caisses" These act as receiving agencies for the premiums and as disbursing agencies for the payment of claims A certain proportion of the premiums must be forwarded by the caisses to the regional or central bureau, as a guaranty fund During 1934-1935 many of the caisses paid out more for claims than they received in the form of premiums Hence they have been obliged to draw on their reserves This deficit amounted to 48 million francs in 1935 and to 44 million in 1934, half of which was for milk tickets when the mother was unable to nurse her infant

The expenses of administration of social insurance were 85 million francs in 1934 and rose to 95 million in 1935 The decrease in premiums received during these two years and increase in administrative expenses have resulted in a deficit in the total budget, which at the end of 1935 amounted to 77 million francs The caisses have no reserves with which to balance the 1937 deficit, which will be still larger This is a serious situation, according to Dr Dordives, who has analyzed the report of the minister of labor in the July 1 issue of *Siècle medical*

The Hippocratic Oath and Social Insurance

The Hippocratic Oath was the subject of a lecture delivered by Dr Legros at the Faculté de médecine, which appears in the *Siècle medical* of July 1 The tendency in many countries to spread the application of social medicine raises the question of whether the limits of professional secrecy in its relation to social medicine in general and sickness insurance in particular should be as sharply drawn as they have been in the past Medical control in sickness insurance has as its chief objective not only to corroborate the actual presence of an illness but to ascertain the cause, no matter whether the incapacity to work has existed for some time or the insured person has already returned to work and made a claim for compensation The social insurance office which pays a sickness benefit has the legal right to investigate, through its medical inspectors, the validity of such a claim When an insured person becomes ill he is obliged to pay for all medical care and to have been completely cured before he receives any compensation from the local social insurance office Only 80 per cent of the total outlay is assumed by the insurance office, the insured person paying the balance as his share of the total, unless the incapacity to work is a prolonged one

At the beginning of 1934 more than one fourth of the population of France was covered in case of sickness or maternity by social insurance, so it is not surprising to learn, according to Dr Legros, that the "absolutism," as he terms it, of professional secrecy is changing as the result of the widespread application of social insurance The social insurance law

authorizes local compensation bureaus to make the necessary expenditures to conduct an independent investigation in any case in which there is the least doubt about a claim for sickness or maternity incapacity to work This, however, if carried out to any extent, would lead to an enormous increase in the costs of administration Professional secrecy, according to Dr Legros, is entirely incompatible with social prophylaxis, in the majority of cases, and hence it should be abandoned so far as social medicine is concerned Professional secrecy is justified only when the information given to the attending physician is of such a nature that its transmission to a third party would work an injustice to the insured The oath of Hippocrates was quoted as having been applicable in the era when social hygiene and social insurance were not even thought of In that era the patient-doctor relation was still individualistic and any secrets revealed by the patient were jealously guarded Two new developments necessitate a modification the danger of contagion requires subordination of the rights of individuals and the introduction of social laws accompanied by the underlying principle of interhuman solidarity A law that has been in force since 1902 obligates the physician to report every case of contagious disease Experience shows that only the acute infectious diseases, such as scarlatina, variola or measles, are reported, but none of the so-called social diseases It is certainly in the interest of the insured that the caisses or disbursing bureaus of the social insurance should be notified in the case of an insured having tuberculosis As to venereal and mental diseases, there should also be no reluctance, if the attending physicians know that all records are kept secret With the more widespread application of social insurance, professional secrecy is losing more and more of its importance here

The National Health

A new long time program has been mapped out in the province of industrial hygiene Systematic nation wide examinations of the general health and fitness for work of all persons engaged in industry are to be undertaken, and every member of the medical profession will be called on to participate in this survey At a great demonstration that marked the inauguration of this drive, the national führer of physicians, Dr Wagner, referred to the fact that despite the many measures undertaken by the government in the matter of the health and working capability of the German people there still remained much to be accomplished Formerly no attention was paid to the physical condition of the worker unless he became ill Thanks to this indifference, 35 per cent of the present-day population of Germany have become invalid before the age of 65 It is manifest that prophylactic attention to health should have its inception while the worker is still enjoying good health The following measures are envisaged by the present plan 1 Standardized "health albums" on the basis of new medical examination 2 Sanitary corps trained in industrial hygiene, the members of these corps to cooperate with the medical officers in the maintenance of adequate sanitary regulations and supervision of the workers' health This supervision shall extend to the leisure time activities, participation in sports, family life and nutrition of each worker 3 Simultaneous reorganization of the social insurance Health passes will also be issued in the four districts in which industrial health examinations shall have already taken place This "pass" is a pocket-size certificate that contains a detailed personal history of the examinee, the data elicited by the examining physician are recorded in a table in cipher The "health album" contains data on the ancestry, bodily weight, physique, functional tests, physical defects and type of occupation The health pass contains information with respect to follow-up

examinations, illnesses and the names of the attending physicians, participation in party-sponsored excursions and participation in sports. This pass must be submitted by the worker at the time of medical examination and in case of illness. It will thus be possible for the medical officers to have ready access to the records of previous examinations in case the worker should change his place of employment or his attending physician.

Congress on Medical Aspects of Aviation

The Association of Commissioned Teachers of Aeronautic Hygiene, a group of instructors who are duly commissioned to lecture at the German universities on the medical aspects of aviation, met recently at Bad Nauheim. The principal topic of discussion was the sympathetic nervous system. The first speaker, E. Koch of Bad Nauheim, offered an account of the place of the sympathetic system in the functional scheme of the organism as a whole. The interrelation of the psyche and the sympathetic nervous system was discussed by H. Lottig of Hamburg, who called attention to the fact that the psychic-vegetative processes play an important part in the lives of fliers. D. Jahn of Freiburg spoke on the interrelation of the sympathetic and metabolism and its bearing on aeronautic hygiene. He outlined the different sympathetic nervous reactions on the basis of carbohydrate metabolism, the regulation of blood pressure and the acid-base economy. R. Herbst of Kiel discussed the clinical aspects of sympathetic neuroses and their significance for the fitness to fly. E. A. Müller of Münster discussed the modifications of the sympathetic system brought about by athletic training and what sort of bodily training, if any, is of specific use for the adaptation and working capability of an aviator. Other papers concerned the interrelation of the sympathetic nervous system and the vestibular apparatus, especially with respect to the pupils and the circulation, air sickness, dangers of carbonic acid inhalation at high altitudes, new data on the limits of a person's endurance of centrifugal forces and so on.

Professional News Notes

A Physician's Social Aid has been organized by the welfare section of the National Chamber of Physicians. This makes it possible for the chamber to grant on request financial aid for needy physicians and their families. This aid is extended only if the physician cannot receive adequate assistance from other physicians' benefit organizations or from his relatives. No aid is extended to a doctor who finds himself in bad financial straits through abuse of his credit. A physician has no legal right to demand this assistance; the granting of it lies solely within the discretion of the National Chamber of Physicians, which also stipulates the exact amount of an advance and when it is to be repaid. No aid will be extended unless the total income of the physician in question falls short of a certain minimum necessary for existence. Minimal monthly living incomes are rated as follows: doctor living alone, 100 marks; married doctor, 120 marks; doctor's widow, 80 marks; completely orphaned children of doctors, from 30 to 75 marks; children unprovided for, 20 marks for each child. So far as the total income falls short of these minimal sums, the difference will be supplied by the social aid. The recipient of the benefit should, however, make an effort to increase his or her income; a doctor's widow, for example, if physically able, is expected to try to earn her own living. Whenever possible the amount granted should be repaid to the organization. The aid should be considered fundamentally as a noninterest-bearing loan. Collateral, if such exists, is posted by the recipient of the aid. The necessary funds for social aid service are raised by a surtax levied on all members of the National Chamber of Physicians.

According to reliable authorities, all financial assistance to German physicians will ultimately become standardized. The purpose is not to guarantee assistance to a doctor as if it

were a sort of official pension, but the attempt will be made to secure for all medical men a legal right to a living income.

The national *fuehrer* of physicians has decreed a new arrangement with respect to charitable institutions for the sick. Latterly it has repeatedly happened that physicians on the staffs of sectarian hospitals have been discharged because of withdrawal from the particular religious group to which the institution belongs. Church authorities justify this action on the basis of old rules or widespread tradition to the effect that a physician who serves in a sectarian charitable institution must be a communicant of the church in question. Such stipulations, says the national *fuehrer* of physicians, belong to the *anschauungen* of another day. The Nazi view is that religion and confession are private affairs and, since the party in no way undertakes to prescribe in matters of religious belief, it conversely refuses to recognize the extension of religious considerations into secular affairs. On this basis the removal of members of a hospital staff because they have ceased to be communicants of a church is officially regarded as inequitable. In order to protect those physicians who find their position on the staffs of charitable institutions jeopardized because of the foregoing sectarian considerations, the medical *fuehrer* has declared it illegal for a German doctor to accept any position in a charitable hospital if the former incumbent has been discharged because of his withdrawal from a particular church.

Foundation of a Japanese-German Medical Society

As every one knows, a close cooperation between German and Japanese physicians and scientists in general has existed for decades. This rapport was in great measure due to the enormous influence exerted by Robert Koch in his time on the learned world of Japan. Many Japanese physicians have studied in Germany, have a knowledge of the German language and make particular use of German medical literature. Recently a Japanese-German Medical Society has been founded in Tokyo which numbers among its officers not only the leading scholars of Japan but the German ambassador as well. The new organization will foster such activities as the exchange of books, the publication (in German) of the results of scientific research and in addition the exchange of students, professors, research workers and medical officers.

The Sequels of Gonorrhea

Dr. Schaefer has undertaken a follow-up investigation of the sequels of ascending gonorrhea among patients treated at the women's clinic of Greifswald University during the past decade. Of 205 cases, only seventy-two could be evaluated for statistical purposes since the rest were lost to view. Of these seventy-two women, 40 per cent presented chronic complaints which lasted for years subsequent to the initial course of treatment at the clinic. 18 per cent suffered from menstrual disorders and 21 per cent required eventual surgical interventions after further clinical treatment; in two cases, for example, operations for tubal pregnancy were performed. Of fifty-eight married women patients, approximately one fourth subsequently brought children into the world. Schaefer found that if a wife presents ascending gonorrhea not only will the marriage probably be sterile but the disease tends to produce sequels of years' duration which may well require surgical intervention, and the latter is always of a mutilating character.

Jubilee of the Leopoldine Academy

The Kaiserlich-Leopoldinische Akademie (Imperial Leopoldine Academy) of Halle an der Saale celebrated the 250th anniversary of its foundation. The founder was Dr. Bausch, a physician of Schweinfurt, Bavaria. After a somewhat checkered career the academy was removed to Halle where a few decades ago Professor Abderhalden, the physiologist, succeeded in arousing it to a more active life. The academy possesses a library of 120,000 volumes and publishes a journal, the *Acta Leopoldina*. In addition it awards the Cothenius medal.

for distinguished scientific contributions. The celebration was marked by the reading of a series of jubilee lectures the themes of which included the most diverse scientific fields.

ITALY

(From Our Regular Correspondent)

July 15, 1937

Mutual Insurance for Industrial Diseases

A convention was recently held for establishing the standards for administration of medical services to those insured in the *Casse Mutue Malattia dell'Industria*. The insured may select their own physician. The houses of mutual insurance will provide ambulant hospitals in which the insured will be given preventive treatments, care of diseases that have to be treated by specialists, general treatment of diseases that do not hinder the patient from work and examinations for verification of conditions reported.

Patients cannot change from one physician to another in the course of a disease, but they may select another physician in a new illness. The conditions of payment for medical care will be arranged between provincial representatives of the houses of mutual insurance and of the syndicate of physicians. Physicians who work for mutual insurance organizations are appointed for the year. A special committee is in charge of the fulfilment of the established standards.

Centers for Care of Hygiene and Sanitation

During the debates on the balance of account of the Ministeriat of Internal Affairs, which took place recently in the lower house, some changes in the laws concerned with the administration of social services were suggested. The campaign against infantile tuberculosis is left in the hands of municipal physicians, who are not well prepared for the task. Deputy Pentimalli believes that municipal physicians should take a course in pediatrics with specific preparation during their studies in universities. Aside from that certain reforms in hospitals and homes for children are necessary. It is advisable that the establishment and functioning of homes for children between the ages of 4 and 6 years be a task of the *Opera nazionale per la protezione della Maternita e Infanzia* because of the fact that the need has not been provided for. Mr. Bufarini Guidi, the undersecretary of state, reviewed the health conditions of the country during 1936. Regardless of the fact that families and soldiers have been recently transferred from Italy to Italian Africa, there have been no cases of tropical diseases reported. The few cases of amebiasis that have been reported were not grave and were controlled in time. Cases of acute anterior poliomyelitis and epidemic influenza have been reported. In certain large cities the mortality from influenza increased in comparison to that of previous years. Antidiphtheria and antityphoid vaccines were administered to larger numbers during the last year than previously.

Study of the Hearts of Soldiers

At the recent International Congress of Sport Medicine, Lieut. Prof. Ugo Casanis reported the results of studies on the size and functions of the heart of 111 soldiers, including those who had indulged in sports and those who had not done so before entering the military service. He used Benedetti and Bollini's method of the three measures of the heart. The method consists in determining the anteroposterior, transverse and longitudinal diameters by teleroentgenography. By multiplying first the three lineal measures and then the product of the multiplication by 0.45, which is the coefficient of correction, a cubic value is attained which is known as the tridimensional value of the heart. This figure shows closely the real size of the heart of living persons. The speaker said that the volume of the heart is proportional to the height of the individual but

that the organ is larger in sportsmen than in those who are not given to such exercise. The transverse diameter, which up to now has been considered an index of the size of the heart, oscillated between 122 and 147 cm in the group of athletic soldiers and between 107 and 142 in the sedentary group. According to the speaker it is advisable to abandon the determination of the transverse diameter by itself as a method for determining the volume of the heart and to use, instead, the tridimensional method, which gives more exact figures as to the volume. Height, the somatic constitution, vital capacity, arterial pressure and the rapidity of reestablishment of respiration are better in athletic than in nonathletic soldiers. The rate of pulse and of respiration are diminished in the soldiers who are active.

Atropa Belladonna in Parkinsonism

Professor Gandelini, in a lecture before the *Societa Medico-Chirurgica di Pavia*, reported results of pharmacologic studies on a decoction of atropa belladonna in the treatment of post-encephalitic parkinsonism. He studied the changes of the body weight, glycemia, Wellmann's test and the behavior of the nitrogen, chlorides, bilirubin and cholesterol in the blood of patients with postencephalitic parkinsonism after administration of atropa belladonna for nine or ten months. In some of the patients the Donaggio and Buscaino tests were performed and the basal metabolism was determined. He reached no conclusions because of the fact that the treatment has to be given for a long time without any interruption in order to see its effects.

Death

Prof. Ferdinando Michel, the director of the *Clinica medica* of the Turin University and a senator, is dead. He wrote important articles on blood diseases, epidemic encephalitis, renal diabetes, the serodiagnosis of cancer, hemolytic splenomegaly, and jaundice. He was the founder of the *Centro antituberculoso* of Turin and associated director of the *Centro Studi per i tumori*. He was a fellow of several scientific academies and a member of several philanthropic and sanitary associations.

Marriages

STEPHEN STOCKTON WOOLSTON, Philadelphia, to Miss Elizabeth VAUX Ingersoll of Penlynn, Pa., June 5.

FAUNTLEROY HARRIS SCHNAUSS to Miss Jewell Edith Wiggins, both of Jacksonville, Fla., June 5.

FRANK I STAYER West Chester, Pa. to Miss Jean Elizabeth Fulton of Brandywine Manor, July 9.

WYMAN PLATE STARLING, Roseboro, N. C., to Miss Flossie Kathleen Cogdell of Goldsboro, June 18.

EDWARD FULLER STANTON to Miss Margaret Gilmore Pendleton, both of New York, June 19.

JOSEPH WILLIAM STRAYER, Lafayette, Ind., to Miss Evelyn Westcott Carr of Richmond, May 22.

ROBERT C WINSLOW, Sylacauga, Ala. to Miss Virginia Kirby of Marion Junction, May 30.

JAMES JOHN CLARK, Janesville, Wis., to Miss Phyllis Perrig Nott of Richmond, April 28.

HERBERT C WOOLLEY, Pennhurst, Pa., to Miss Henrietta C Beman of Emporia, Va., April 3.

RICHARD WILLETT SOLIER, Bryan, Ohio, to Miss Erma Louise Sprague of Coschocton, June 19.

LOUIS CARROLL ROBERTS to Miss Jessie Speight Ward, both of Durham, N. C., April 23.

PAUL H WATSON, Newburgh, N. Y., to Miss Virginia Elizabeth Jackson, June 16.

EMIL F STEINKAMP to Miss Lydia Poetker, both of Huntingburg, Ind., July 3.

PAUL C WAGNER to Mrs. Irma Grotclueschen, both of Milwaukee, April 30.

GRACE E WILLIAMS to Mr. J. Frank Field, both of Iowa City, May 26.

Deaths

Joseph Leggett Miller * Chicago, since 1924 clinical professor of medicine at the University of Chicago, died suddenly of heart disease, August 6 at a mountain ranch near Great Falls Mont. aged 69. Dr. Miller was born in Kewanee Ill. Nov. 24, 1867. He was educated at the University of Michigan, Ann Arbor where he received the bachelor of science degree in 1893, in 1895 he received the medical degree from Northwestern University Medical School in Chicago. From 1897 to 1924 he was at Rush Medical College serving as instructor of bacteriology from 1897 to 1899, instructor in medicine from 1901 to 1905 assistant professor from 1905 to 1909, associate professor from 1909 to 1919, and professor from 1919 to 1924. He was secretary of the Section on Practice of Medicine of the American Medical Association from 1903 to 1908, chairman, 1908-1909 and in 1928 a member of the House of Delegates. He was a member of the Association of American Physicians, the American College of Physicians, the American Society for Clinical Investigation and the American Committee for the Control of Rheumatism of the Ligue Internationale. In addition, he had served as president of the Chicago Society of Internal Medicine and the Institute of Medicine of Chicago. During the World War, he served first as major and later as lieutenant colonel in the medical corps of the U. S. Army. In 1933 he received the honorary degree of doctor of science from the University of Michigan. He was attending physician to St. Luke's Hospital and formerly attending physician to the Cook County Hospital. Dr. Miller also served the American Medical Association as editor in chief of the *Archives of Internal Medicine* from its inception in 1909 until 1931. He was the author of numerous contributions to medical literature and was especially influential as a practitioner of clinical medicine.

Nellis Frances Witter Stephenson, Washington, D. C., Boston University School of Medicine, 1892, served the Puerto Rican government as teacher, and superintendent of schools, in clinical and hospital work, and as an inspector of health from 1908 to 1918, was appointed a contract surgeon in the U. S. Army in September 1918 and served until June 30, 1919, in the same year was appointed acting assistant surgeon in the U. S. Public Health Service, in 1920 was made special expert in charge of the eye, ear, nose and throat section of the medical division of the Bureau of War Risk Insurance, now the Veterans' Administration, senior medical consultant to the Board of Veterans' Appeals, Veterans' Administration, aged 67, died, May 29, of hypertension and heart disease, at the home of his son at Carolina Beach, N. C.

Leroy Philip Kuhn * Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, fellow of the American College of Surgeons, president of the staff of the Lutheran Memorial Hospital, attending surgeon to the Columbus Hospital, associate surgeon to the Augustana Hospital, chief surgeon to the Lumbermen's Mutual Casualty Company, served during the World War, aged 57, died July 23, at his summer home in Three Rivers Mich. of heart disease.

James William Osborn, La Feria, Texas, Iowa Eclectic Medical College, Des Moines, 1888, Medico-Chirurgical College of Philadelphia, 1901, member and at one time secretary of the Iowa State Medical Society, past president of the Polk County (Iowa) Medical Society, served during the World War, formerly instructor in dermatology at Drake University College of Medicine, Des Moines, at one time on the staff of the Iowa Methodist Hospital, Des Moines, aged 73, died, May 21.

Charles Vernon Patchin, Dansville N. Y., Bellevue Hospital Medical College, New York, 1881, formerly village health officer and state sanitary supervisor for Livingston, Wyoming, Genesee, Monroe, Ontario and Wayne counties, 1914-1917, aged 83, died, May 30, in the Strong Memorial Hospital, Rochester, of heart disease and arteriosclerosis.

Jason Tyson, Santa Anna, Texas, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897, member of the State Medical Association of Texas, past president and secretary of the Coleman County Medical Society, for many years member of the school board, aged 69, died, May 13, of carcinoma of the liver.

Frank W. Baylor * Chicago, Hospital College of Medicine, Louisville, Ky., 1904, Hahnemann Medical College and Hospital, Chicago, 1907, attending surgeon to the Alexian Brothers, Henrotin, Chicago Memorial and Columbus hospitals, aged 54, was killed, July 23, in an automobile accident near Lebanon, Ind.

Theodore Burton Appel * Lancaster Pa., University of Pennsylvania Department of Medicine Philadelphia 1894, secretary of health, Pennsylvania State Department of Health,

from 1927 to 1935, past president of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, served during the World War, medical director of the Lancaster General Hospital, 1906-1920, and later a member of the staff, aged 65, died, July 31.

Clarence Lamoine Power, Temple, Texas, Kentucky School of Medicine, Louisville, 1892, member of the State Medical Association of Texas, served during the World War, postmaster, formerly on the staff of the King's Daughters' Clinic and Hospital, aged 67, died, May 24, of coronary thrombosis.

George Michael Goddard, Waxahachie, Texas, Kentucky School of Medicine, Louisville, 1895, member of the State Medical Association of Texas, past president of the Ellis County Medical Society, health officer of Waxahachie, aged 69, died, May 11, in a hospital at Dallas, of carcinoma of the stomach.

Arthur Joseph Savard, New Britain, Conn., Tufts College Medical School, Boston, 1919, member of the Connecticut State Medical Society, served during the World War, formerly police surgeon, aged 45, on the staff of the New Britain General Hospital, where he died, May 31, of coronary occlusion.

Joseph Michael Toner, San Francisco, University of California Medical Department, San Francisco, 1901, at one time city supervisor and coroner, formerly director of the California State Department of Institutions, aged 67, died, July 22, of carcinoma of the stomach and arteriosclerosis.

Joseph B. Shaw, Hot Springs National Park, Ark., University of Arkansas School of Medicine, Little Rock, 1905, member of the Arkansas Medical Society, formerly coroner, for eight years president of the city board of health, aged 57, died May 28 in Detroit of carcinoma of the stomach.

Fredrick Wallace Logan, Blue Earth, Minn., State University of Iowa College of Medicine, Iowa City, 1901, member of the Minnesota State Medical Association, on the courtesy staff of the Blue Earth Hospital, aged 64, died, May 29, in the Abbott Hospital, Minneapolis, of coronary thrombosis.

Claude Le Baron Sigler * Pinckney, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895, formerly village president and bank president, member of the school board, medical superintendent and owner of the Pinckney Sanitarium, aged 64, died, May 22.

David Aaron Hart, Dorrance, Pa., Baltimore Medical College 1903, member of the Medical Society of the State of Pennsylvania, formerly on the staff of the Nanticoke (Mass.) State Hospital, aged 64, died, May 14, of heart disease and chronic interstitial nephritis.

JOSEPH LEGGETT MILLER, M.D., 1867-1937

Clive Sidney McGinnis ♂ Parsons, Kan, Washington University School of Medicine, St Louis, 1909, past president of the Labette County Medical Society, medical superintendent of the State Hospital for Epileptics aged 59 died May 14 of diabetes mellitus

George M Ruffin, Washington, D C, Columbian University Medical Department, Washington, 1902, member of the Medical Society of the District of Columbia, aged 60 died, May 29, in Clover, Va, of coronary occlusion and arteriosclerosis

Roy Alvin Schnacke, McGregor, Minn, Minneapolis College of Physicians and Surgeons, 1909, member of the Minnesota State Medical Association, formerly police surgeon in St Paul aged 50, died, May 21, in a hospital at Brainerd, of heart disease

William J Brewer, Perryton Texas (licensed in Texas, under the Act of 1907), member of the State Medical Association of Texas, health officer of the city of Perryton and Ochiltree County, aged 65, died, May 1, in a local hospital

Dayton L Kathan ♂ Schenectady, N Y, Albany Medical College, 1886, fellow of the American College of Surgeons, consulting surgeon to the Ellis Hospital, aged 80, died suddenly, May 13 of angina pectoris and arteriosclerosis

Alvin Stackhouse Rogers ♂ Trenton, N J, Medico-Chirurgical College of Philadelphia, 1916, on the staff of the Mercer Hospital, aged 47, died, May 23, of a blood stream infection of *Streptococcus viridans* and endocarditis

Clark Hilton Rice ♂ Montgomery, Ala, Tulane University of Louisiana School of Medicine, New Orleans, 1903, at one time instructor in diseases of children at his alma mater aged 56, died suddenly, May 27, of coronary occlusion

Gordon Warren Rice, Watervliet, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903, aged 69 died, May 11, in the Mercy Hospital, Benton Harbor, of uremia and of cerebral hemorrhage

Francis A Keenan, Newport, R I, College of Physicians and Surgeons, Baltimore, 1902, formerly city physician, on the staff of the Newport Hospital, aged 59 died May 28 in the Newport Hospital of cerebral hemorrhage

Lee Orrion Foster, Sunray, Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University, 1910, served during the World War, aged 56, died, in May, in a hospital at Amarillo, of pneumonia

William Joseph Duncan, Washington, D C, Georgetown University School of Medicine, Washington, 1925, formerly associate professor of anatomy at his alma mater, aged 37, died, July 8, of strychnine poisoning

Cyrus Job Severance, Mannsville, N Y, University of the City of New York Medical Department, 1888, aged 74, died, May 28, in the Oswego (N Y) Hospital, of injuries received in an automobile accident

Susan Dora Wilson Peyton, St Louis, Homeopathic Medical College of Missouri St Louis, 1900, aged 80, was found dead in bed, May 12, of heart disease, at the home of her sister in Paxton, Ill

Wilmer Clinton Kellogg Syracuse, N Y, Albany (N Y) Medical College, 1884, member of the Medical Society of the State of New York, aged 77, died, May 31, of diabetes mellitus and arteriosclerosis

James Buchanan Prichard, St Louis, Missouri Medical College, St Louis, 1885, at one time professor of pathology at Barnes Medical College, aged 77, died, May 11, in the Bethesda General Hospital

James Berkley Settle, Sandgap, Ky, University of Louisville Medical Department 1892, aged 72, died May 12, in the Berea (Ky) College Hospital of injuries received when struck by an automobile.

Joseph D Napoleon Dubeau, Warren R I, School of Medicine and Surgery of Montreal, Que, Canada, 1882, aged 81 died May 27, of diabetes mellitus cerebral hemorrhage and pneumonia

Edward Stanton Imel Sr, El Paso, Texas, University of Louisville (Ky) Medical Department, 1892, served during the World War, aged 74, died, May 29, of myocarditis and arteriosclerosis

Charles Howard Harbinson ♂ Rensselaer, N Y, Albany Medical College, 1925 health officer of Rensselaer aged 35 died May 3 in the Memorial Hospital, Albany, of illuminating gas poisoning

Robert Blake Griffith, Los Angeles, University of Southern California School of Medicine Los Angeles 1904, aged 60, died May 31, of injuries received in an automobile accident

James M Scott ♂ Topeka, Kan University of Kansas School of Medicine, Kansas City, 1922, vice chairman of the state board of administration aged 44 died May 13 of angina pectoris

Robert Huse Purple, Atlanta, Ga University of Vermont College of Medicine, Burlington, 1897, served during the World War, aged 62 died, May 10 of pulmonary tuberculosis

John Gartrell Johns, Hettinger, N D, University of Nashville (Tenn) Medical Department 1897 aged 71 died May 22, of myocarditis arteriosclerosis and senile dementia

Krikor Jelal, New York, Universite de Paris Faculte de medecine, France, 1896, aged 68, died, May 12, in Manchester Township, of cerebral hemorrhage and chronic myocarditis

John Thomas Lyston, New York, University of Vermont College of Medicine, Burlington, 1895 member of the Medical Society of the State of New York, aged 67 died, May 15

Roscoe John Taylor, East Nassau, N Y, Albany (N Y) Medical College 1896, health officer of the town of Nassau, aged 65, died, May 19, of carbon monoxide poisoning

Harry H O'Kelly, Portageville Mo, Barnes Medical College, St Louis, 1900, aged 82, died, May 31, as the result of injuries received in a fall five months previously

James Cogswell Du Maresque Pigeon, Boston, Harvard University Medical School Boston 1883 member of the Massachusetts Medical Society, aged 82, died, May 21

Waldo Henry Richardson, New York College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878, aged 80, died, May 31

Henry Heydt Herb, Trexlertown Pa, Medico Chirurgical College of Philadelphia, 1904, aged 65, died, May 11, of coronary occlusion and arteriosclerosis

William Forest Dailey ♂ Terra Alta W Va, Louisville (Ky) Medical College, 1894, aged 68, died, May 12, in the Memorial Hospital, Cumberland, Md

Edward Payson Childs, Cedar Rapids, Iowa, Hahnemann Medical College and Hospital, Chicago, 1903, aged 82, died, May 9, of carcinoma of the intestine

Guy De Nuys Conover, Santa Monica, Calif, Indiana University School of Medicine, Indianapolis, 1908 aged 52, died May 1 of coronary occlusion

Cicero Gibson, Thomson, Ga, Atlanta Medical College, 1889, member of the Medical Association of Georgia, also a druggist, aged 70 died, May 30

Chauncey Williams Norton, Cazenovia, N Y, Harvard University Medical School, Boston, 1900, aged 62, died, May 28, of cerebral hemorrhage

George W Hargest, Seachiff, N Y, Bennett College of Eclectic Medicine and Surgery, Chicago, 1887, aged 88, died, May 26, of chronic myocarditis

Frederick Louis Rabe, Lowden, Iowa, State University of Iowa College of Medicine, Iowa City, 1892, aged 85, died, May 23, of bronchitis

Clark McPherrin Carr, Coshocton, Ohio Hospital College of Medicine, Louisville, Ky, 1897, aged 78, died, May 22, of heart disease

James Paul Henderson, Chicago Miami Medical College, Cincinnati, 1885, aged 73, died, May 24, in St Luke's Hospital, of heart disease

Jonathan H Allen, Norwich, Conn, New York Homeopathic Medical College and Hospital, New York, 1888, aged 78 died in May

Lola Annetta Johnson, Portland, Ore, Medical College of Indiana Indianapolis, 1898, aged 75, died, May 27, of valvular heart disease

Eddie Abram Gullede, Memphis Tenn, Memphis Hospital Medical College, 1903, aged 64, died, May 17, in Leavenworth Kan

John Francis Ten Eyck, Toronto Ont, Canada Trinity Medical College, Toronto, 1899, aged 72, died, May 5

William T Morrow ♂ Loysville, Pa, Baltimore Medical College 1908, aged 61, died, May 29, of syringomyelia

Henry David Rowe, Orangeburg S C Leonard Medical School, Raleigh, N C, 1903, aged 67, died in May

Lewis Rothman, Wittenberg Wis, Rush Medical College, Chicago, 1887 aged 75, died May 28, of pneumonia

Edward Thomas Murray, New York, Baltimore Medical College, 1898, aged 63, died, May 7

Sarah Lucretia Robb, Gainesville, Fla (licensed in Florida in 1894), aged 84, died, May 2

Correspondence

CROSS REACTIONS IN AGGLUTINATION TESTS

To the Editor—The incitants of typhoid fever, undulant fever and tularemia differ from one another in cultural characteristics. So-called cross reactions may occur, however, in agglutination tests with specimens of blood from some of the patients with these infections. Edward Francis (Symptoms, Diagnosis and Pathology of Tularemia, *THE JOURNAL*, Oct 20, 1928, p 1155) has called attention to reactions with *Brucella abortus* in serums from patients with tularemia. According to Gilbert and Coleman (Incidence of Tularemia in New York State, *Am J Pub Health* 22 1249 [Dec] 1932) the blood from patients with undulant fever rarely has been found to agglutinate *Bacterium tularense*. Occasionally, however, *Bacillus typhosus* may be agglutinated. An example of the confusing serologic reactions which sometimes are obtained may be of interest. A young man developed undulant fever, with the date of onset in June 1936. His blood was found to agglutinate *Bacillus typhosus* definitely and a diagnosis of typhoid fever was at first considered. The symptoms mentioned were chills, sweating, headache, backache, pains in the joints and general malaise. The temperature varied from normal in the morning, when the patient felt fairly well, to 104 F in the afternoon. He was still in the hospital late in August. Specimens of blood received August 14 and 18 agglutinated *Bacillus typhosus* in a 1:320 dilution of the serum and *Brucella abortus* in a 1:2,500 dilution. A specimen received August 22 agglutinated *Brucella abortus* in a 1:10,000 dilution of the serum, while the titer with *Bacillus typhosus* was slightly diminished. A definite history of typhoid fever or the administration of typhoid vaccine was not obtained, although there was a question that the patient might have had such an infection or received vaccine in 1921, when his brother had typhoid fever.

SENSITIVITY OF THE KOLMER COMPLEMENT FIXATION TEST

To the Editor—In the editorial entitled "The Clinician and the Serologic Test for Syphilis" (*THE JOURNAL*, July 10, p 134) it is stated that, in the two studies of the American Committee on Evaluation of Serodiagnostic Tests for Syphilis, this test as conducted in my laboratory gave 72.6 per cent positive reactions with specimens from syphilitic individuals.

As a matter of fact, however, in the first survey (The Evaluation of Serodiagnostic Tests for Syphilis in the United States, *Ven Dis Inform* 18, supplement 1, May 1937) it gave 75.9 per cent positive reactions in a group of 415 serums and 77.8 per cent positive reactions in a group of 110 spinal fluids from syphilitic individuals. And in the second survey, recently completed, it gave 87.2 per cent positive reactions (personal communication from Dr W L Treadway, acting surgeon, U S Public Health Service, April 20, 1937) with the serums of syphilitic donors, the increased sensitivity of the reaction being probably due to an improvement in the antigen and more particularly to the employment of larger amounts of serum. Kolmer, J A. Changes in the Technic of the Kolmer-Wassermann Test, *Am J Syph & Neurol* 19 481 [Oct] 1935. In the first survey my test gave 0.7 per cent falsely positive reactions with 468 serums but none with 110 spinal fluids from presumably nonsyphilitic persons. In the second survey specificity was 100 per cent (personal communication from Dr Treadway).

Therefore, my complement fixation test gave 77.8 and 87.2 per cent positive reactions respectively with the serums of syphilitic donors in the two surveys, or an average of 82.5 per cent instead of 72.6 per cent stated in the editorial, 87.2 per cent more nearly expresses its sensitivity with the improvements in technic now employed.

I shall appreciate your kindness in publishing a correction in the interests of scientific accuracy.

Director, Research Institute of Cutaneous Medicine

"ARTERIOSCLEROSIS AND THROMBOANGIITIS OBLITERANS"

To the Editor—In *THE JOURNAL* June 19, page 2102, appeared an article by Drs Bernheim and London on "Arteriosclerosis and Thrombo-Angiitis Obliterans, Report of Cases and Treatment." This article confirms work which I initiated in 1921 and which has been carried on for a number of years since that time, work reported, in part, in the issue of *International Clinics* of September 1925. It was gratifying to find that these authors confirmed the statement made therein to the effect that a solution of sodium citrate combined with sodium chloride and buffered with dibasic potassium phosphate to a pH of 7.6 is very effective in the treatment of thromboangiitis obliterans and arteriosclerosis obliterans, nowhere, however, in this article by Drs Bernheim and London is mention made of the fact that this solution was described by me in detail in the article which appeared in the *International Clinics* of September 1925 as follows:

Since the purpose sought was to prevent coagulation by increasing the alkalinity of the blood we decided to prepare the solution in such a fashion so as to obtain the desired hydrogen ion concentration. In addition we thought it important to maintain a certain percentage concentration of sodium citrate so as to conserve the property that this drug has in inhibiting bacterial development and favoring phagocytosis. We also found later that the change in quantity of sodium chloride added to the solution produced a favorable clinical effect and appreciably modified the development of a chill following the injection of the solution. To produce a certain hydrogen ion concentration and to maintain it at a desired level it is necessary to add buffer salts. The importance of buffering this solution may be seen from the fact that sodium citrate dissolved in normal saline not only exercises the same analgesic effect but also prolongs the coagulation time. The addition of dibasic potassium phosphate was found to be of even greater value inasmuch as it is an anticoagulant and when present in certain concentrations prevents the occurrence of the severe chills which followed the use of sodium citrate alone dissolved in water. It also rendered the citrate effective in a much smaller dose than formerly employed. The solution as administered is prepared by dissolving 70 grams of sodium citrate (Squibb) in 1,000 cc of freshly prepared doubly distilled water to which 3 grams of sodium chloride (Squibb) are added. It usually requires the addition of 1 gram of dibasic potassium phosphate (Merck) to render the solution iso-electric as well as isotonic. It is then filtered and sterilized in the autoclave for ten minutes at 110 degrees. One hundred to 250 cc of this solution are injected intravenously every day for ten days and then it is given at two-day intervals for a period of six months. Following this the intervals may be prolonged depending on the condition of the patient. If the latter be free from pain it can be given at weekly intervals for a year. We have found that a solution with a pH of 7.6 to 7.8 gives the best optimum results.

Furthermore, the formula given in the Bernheim and London article is an exact replica of the formula furnished by me to the New York Hospital and prepared in the laboratory of that hospital as far back as 1922. The Bernheim and London article is reported as coming from the Clinic for Peripheral Vascular Diseases, Department of Surgery, New York Hospital and Cornell University Medical College.

It is not my purpose to detract from the value of the article but to emphasize in this connection the fact that this solution, when first initiated was the first which introduced into clinical practice the principle of buffering intravenous injections. I should like to mention the fact that a paper on the use of buffered sodium citrate-chlorides in the treatment of diabetic gangrene was read by title before the Williamsburg Medical Society in 1921, before the Yorkville Medical Society in 1922 and before the Eastern Medical Society in 1923, and the last two papers included case reports of patients treated with this

in the Beth Moses Hospital in 1921 and in St Marks Hospital from 1921 to 1925

To receive confirmation now of a treatment suggested for thrombo-angitis obliterans and arteriosclerosis obliterans as far back as 1921 and published four years later is gratifying

BENJAMIN JABLONS, M.D., New York.

[This letter was referred to Drs Bernheim and London, who reply]

To the Editor—In our paper we made no claim for originality in the use of a buffered solution of sodium citrate in the treatment of thrombo-angitis obliterans, and we are glad to acknowledge that the formula for this solution was originally furnished us by Dr Jablons. We were under the impression that this solution was familiar to every one working in the field. When our paper was prepared we were unaware of the papers on diabetic gangrene read by title by Dr Jablons before the Williamsburg Medical Society, the Yorkville Medical Society and the Eastern Medical Society in 1921, 1922 and 1923.

We differ with Dr Jablons in the explanation of the actions of some constituents of the solution and in the evaluation of some of the factors considered in his letter. An adequate discussion of these differences, however, would require too much detail for consideration here.

ALICE R. BERNHEIM, M.D.
ISABEL M. LONDON, M.D.
New York

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SPOTS BEFORE THE EYES

To the Editor—A man aged 30 weighing 170 pounds (77 Kg) and 6 feet (183 cm) in height has complained of spots floating before his eyes for the past two years. These are always present and are exaggerated in the presence of bright light. At night he notices them while driving as they float by in the glare of approaching automobile head lights and also on looking at the electric light globes. He states that more and more spots seem to be present as time goes on and being of a nervous disposition he continually looks for these and is worried about going blind. His vision checked by a competent ophthalmologist is 20/20 in both eyes without glasses and with correction for corneal astigmatism and hyperopia it is 20/10 in both eyes. Complete ophthalmic examination reveals floating opacities in the vitreous of both eyes. No other pathologic change is visible in either eye by the use of the slit lamp or the corneal microscope. There is no iritis or choroiditis. The retina is normal in all respects and the vessels seem normal. The ophthalmologist has told him to cease looking for these opacities and to return in six months for a check up. The patient describes these opacities as floating strings. Physical examination is essentially negative. Roentgenograms of the teeth, sinuses and chest are negative. The tonsils are out. He has an occasional postnasal dripping associated with some pain in the eye ball. The basal metabolic rate has been -20 on two occasions and the blood cholesterol has been 282 and 270. However the patient seems to be more hyperthyroid than hypothyroid. The blood pressure is 128 systolic 78 diastolic. The Wassermann and Kahn reactions are negative. The blood sugar is 86 mg per hundred cubic centimeters. The urine is normal. The patient is decidedly of a neurasthenic type and on taking thyroid extract 1 grain (0.065 Gm.) daily he complained of fullness in the head and a feeling of excitement within himself. Could these opacities be due to mild hypothyroidism? Would vitamin therapy help? Any suggestion as to treatment and prognosis will be greatly appreciated.

M.D. California

ANSWER—The condition described is common and may be one of three things. The first and rarest is a mild uveal tuberculosis, characterized by a large and ever increasing number of fine vitreous opacities. This is not a stationary condition that persists without change for two years, as in this patient. The second is the common form of vitreous opacities that are due to some toxic condition. In this form the opacities appear suddenly, are annoying to the patient when looking at the blank sky or the printed page and gradually become less dense so that they can be found only when looked for. This

too does not seem to fit the condition described. The third and somewhat uncommon form of vitreous opacities seems to be merely a nonpathologic thickening of the vitreous fibers so that the crossing of two or more fibers casts a shadow on the retina. In this form the opacities appear numerous and arc constantly before the patient when in any bright light, regardless of the fixation. The condition occurs principally in the neurotic type of individual who aggravates the annoyance by searching constantly for the spots. There is no treatment indicated beyond psychotherapy.

HALLUX VALGUS

To the Editor—Will you kindly give me the best surgical opinion with regard to operation for hallux valgus. The patient is 70 years of age in excellent physical condition. How great is the danger of a stiff joint following operation?

M.D. Pa

ANSWER—The treatment for hallux valgus varies with respect to the age of the patient and the degree of arthritis in the metatarsophalangeal joint. The operation of choice in a patient 70 years of age, provided his general physical condition is sufficiently good to justify surgery, consists of excision of the base of the first phalanx, including all its articular surface. After this removal the deforming pressure exerted by the displaced great toe is obliterated. The abduction of the first metatarsal from the second tends to disappear and the correction is thus obtained without weakening the strength of either arch of the foot. The operation more commonly practiced in this country, that of excision of the head of the first metatarsal, has the tremendous disadvantage of weakening both the longitudinal and the transverse arch and disturbs the weight bearing function on the inner side of the ball of the foot.

The operation that is recommended here consists in a straight incision from the first interphalangeal joint to about the mid-portion of the first metatarsal bone, stripping of soft tissue from the base of the phalanx and a transverse osteotomy through about the middle of this phalanx, with removal in one piece of the whole of the proximal fragment. If less bone is removed, a painful fibrous ankylosis is likely to result. The long extensor tendon of the great toe should then be divided subcutaneously well above the site of operation. This removes the bow string-like action which this tendon exerts in maintaining or reproducing the deformity. In most instances the tendon reunites, bridging a wide gap with fibrous tissue, and function is restored after about two months.

The after-treatment consists of placing a small wedge of cotton between the great toe and the second and applying a bandage, which further aids in maintaining the toe in a neutral position. Care should be exercised to avoid overcorrection, since hallux varus is as difficult a problem to treat as hallux valgus. In the average patient this operation does not result in the development of a stiff joint.

NEUROLOGIC SYMPTOMS IN PERNICIOUS ANEMIA

To the Editor—I have a case of pernicious anemia in which the neurologic symptoms have continued to progress for six months after the blood picture has been brought to a practically perfect normal. A search of the literature that is available to me fails to disclose any suggestion for prognosis or therapy. If you could help me in this I should appreciate it very much.

MILES J. BREUER, M.D. Lincoln, Neb.

ANSWER—The treatment of the neurologic manifestations of pernicious anemia is much less satisfactory than the striking results attained by treating the anemia of this disease with liver or stomach preparations. It is of the utmost importance to keep the blood of patients with this disease at a high level of normal as cord changes may progress if the red blood cell count is even slightly below the normal level. This rarely if ever happens if the count is between 4,500,000 and 5,000,000 per cubic millimeter. Also it is probably important that sufficient treatment should be given to cause the cell size, as determined by the mean corpuscular volume, to return to normal. It seems fair to state, therefore, that when the blood is kept constantly within normal limits it is rare for neurologic changes to develop and if these are present when treatment is begun they do not commonly progress.

The treatment is to give sufficient antipernicious anemia medication to produce a satisfactory condition of the blood. If this cannot be accomplished by the oral administration of liver extract or ventriculin, liver extract should be given intramuscularly. Physical therapy such as active and passive exercises and attempts to reeducate the patient in the use of the lower extremities may result in some improvement. About half of the patients who are treated efficiently have subjective improvement but a smaller number have objective evidence of this.

MALIGNANT NEUTROPENIA OR MICROCYTIC
HYPOCHROMIC ANEMIA

To the Editor—I have recently had under my care a white girl aged 10 years with agranulocytosis. Her parents report that she had not been her usual self for the past six months or so and about January 1 of this year she had an attack of influenza, which was treated with home remedies (no drugs) with little effect until January 8 when I was asked to see her for the first time. She then complained of generalized weakness and muscle pains. She was very thin and had a profound paleness which is best described as a waxy pallor. There was vesicular breathing over the left lung without other physical signs of a pathologic condition. She was given acetylsalicylic acid 5 grains (0.3 Gm) three times a day and acetophenetidin 2 grains (0.13 Gm) every two hours for two days, and then for two days the acetophenetidin was reduced to 2 grains every four hours. Her pulse after this medication was 88 and temperature 98.8 F (this was January 13) but she complained of a sore throat. The tonsils were inflamed and enlarged. Acriviolet (1 200) was applied locally to the tonsils. The next day her temperature was 101.5 and pulse 100, and she complained of an extremely sore throat. The tonsils were more swollen and very red and acriviolet was again applied. On the following day (January 15) the tonsils were extremely swollen and red, so 1 per cent silver nitrate solution was used on them and Dohell's solution was prescribed as a gargle. That evening she had a chill and her temperature was 103 and pulse 140 and there was a spot of grayish membrane 0.5 cm in diameter on the left tonsil and a similar patch of membrane on the posterior pharyngeal wall and an area of ulceration of similar size on the right tonsil. A smear showed many Vincent's fusiform bacilli and spirochetes, but a culture showed no growth. The child was hospitalized January 16. A complete blood count showed white blood cells 700 red blood cells, 1,740,000, hemoglobin 40 per cent. The differential showed only a few lymphocytes on the smear. She was given a transfusion of 250 cc of citrated blood (equipment for the direct method was not available) pentnucleotide 10 cc intramuscularly twice a day and yellow bone marrow concentrate 30 minims (2 cc) four times a day and also solution of potassium arsenite 5 minims (0.3 cc) four times a day. Neosarsphenamine solution was used locally for the Vincent's infection. January 17 her temperature remained 105 with pulse 160. January 18 the blood count showed white blood cells 4,800 polymorphonuclears 25 per cent basophils 1 per cent lymphocytes 68 per cent monocytes 6 per cent. She became delirious and died at noon January 18. Autopsy was refused. She had 14 grains (0.9 Gm) of acetophenetidin for two consecutive days then 8 grains (0.5 Gm) for two days and then 6 grains (0.4 Gm) a day for three days making in all 62 grains (4 Gm) of acetophenetidin in seven days together with 105 grains (7 Gm) of acetylsalicylic acid for the same length of time. Do you believe this was agranulocytosis? In your opinion could the agranulocytosis be attributed to this medication? Do you believe considering the history of being 'run down' all the fall and extremely weak and pale when I first saw her, that she had had the disease for some time? Could the influenza give such a low white blood count? Please omit name.

M D Pennsylvania

ANSWER—The history of increasing pallor and weakness, loss of weight and evidence of failing health in this child, sufficient to attract the attention of the parents during the six months prior to the acute infection of the upper respiratory tract is an exceedingly important background for a consideration of the factors responsible for the sequence of events recorded. Apparently the general condition and especially the 'waxy pallor' of the patient when first seen by the physician were distinctly more alarming than might be expected from an attack of "influenza" of one week's duration, and no physical phenomena of significance. Antipyretic drugs were administered at once, though no elevation of temperature is recorded until six days after the patient came under the physician's care, on the eighth day of treatment a chill suggested the first invasion of the blood stream with organisms. Only Vincent's organisms were found on bacteriologic study of the throat flora.

The first blood study, made sixteen days after the onset of the acute symptoms, showed a profound leukopenia with no granulocytes or monocytes present and a hyperchromic or normochromic anemia of severe grade. In a child of this age such an anemia is strongly suggestive of a hypoplastic bone marrow, a microcytic, hypochromic anemia is the usual iron deficiency, nutritional type encountered in young persons. The reticulocyte percentage and a blood platelet count would have helped in the establishment of an aplastic marrow. No jaundice is mentioned and, if a hemolytic organism had overwhelmed the granulopoietic function and destroyed sufficient red blood cells to produce the anemia found, some evidence of excessive hemolysis should have been apparent and other than Vincent's organisms recovered on culture from the throat. The same reasoning might be applied to the possible toxic effect of the drugs used, more especially acetophenetidin, the anemia and symptoms and signs of infection existed 'clinically' prior to any medication and, presumably, some degree of leukopenia antedated the development of progressive throat symptoms and signs, either as a part of a progressive aplastic anemia alone or in conjunction with the depression to granulopoiesis which always accompanies the period of invasion in virus infections. While a moderate degree of leukopenia characterizes "influenza,"

the lymphocytes are usually reduced with a relative increase in polymorphonuclear neutrophils, and the total count seldom goes below 3,000 to 4,000 cells per cubic millimeter.

While sufficient data are not available to make an absolute reconstruction of the sequence of cause and effect in this patient, it would seem most likely that a slowly progressive panhypoplasia of the bone marrow was occurring during the year preceding the acute episode, which terminated in an overwhelming infection initiated by an influenza-like onset. The drug therapy first administered probably had little influence on the course of events and the blood transfusion and pentnucleotide came too late to do more than suggest in the terminal blood count what sometimes may be accomplished in the face of a failing bone marrow. There is one pathogenic organism which may reproduce the acute phase of the clinical picture recorded in this instance, viz, Friedländer's bacillus. The leukopenia follows, however, and does not precede the onset of infection under such circumstances. The degree and type of anemia recorded in the case cited make less likely a true agranulocytic angina of the Schultz type in this child, since red cells and thrombocytes usually remain unaffected.

OXYGEN IN PNEUMONIA

To the Editor—Have reliable statistics been recorded from a sufficient number of cases of lobar pneumonia of the various types to give evidence or proof that the use of oxygen properly administered reduces the mortality or aids in any way the recovery of the patient suffering from pneumonia? Discuss briefly the indications for its use if any and state what physiologic effect it can have for the benefit of the patient and by what process the tissues can use more oxygen than is contained in pure air at proper temperature and altitude, for the majority of patients have ample living tissue uninvolved yet the mortality is high.

O Y JAMES M D, Cooper, Texas

ANSWER—Patients suffering from pneumonia develop anoxia either because the demand for oxygen is increased by reason of increased metabolism or because the area from which oxygen may be absorbed from the lungs is diminished.

Oxygen absorption by the blood is dependent on the gradient between the partial pressure of oxygen in the alveolar air and the partial pressure of oxygen in the blood. Oxygen is ordinarily present in the venous blood at a partial pressure of 41 mm of mercury. The gradient or fall in pressure is about 70 mm. When oxygen is added to the air breathed the concentration of oxygen in the alveolar air is increased, its partial pressure raised and the gradient augmented.

It is possible by increasing the gradient to transmit a larger amount of oxygen through a diminished area in a unit of time so that the hemoglobin more unsaturated than usual becomes saturated. One can readily visualize the analogous procedure of increasing the flow through a narrow vent by increasing pressure when a reservoir of water is raised to increase the flow from the attached tube.

Ordinarily the hemoglobin of the blood is 95 per cent saturated. When the blood is only 93 per cent saturated, cyanosis appears. Rosenbluth and Block published data (Pneumonia Due to Type I Pneumococcus, *Arch Int Med* 58 102 [July] 1936) which showed that when the hemoglobin saturation was only 85 per cent the death rate in pneumonia increased. Oxygen should be administered whenever there is cyanosis, which is evidence of oxygen unsaturation of the blood, or when symptoms produced by anoxia are evident, such as irregular breathing and irregular pulse, confusion and delirium, or whenever the mechanisms that prevent cyanosis are brought into activity, i. e., acceleration of pulse and breathing.

Oxygen may be administered as satisfactorily in many cases by a nasal inhaler leading inside the nostrils as in a tent or with catheters leading to the pharynx, and it should be administered at a flow rate in liters per minute that will increase the content of the alveolar air sufficiently to overcome evidence of anoxia.
